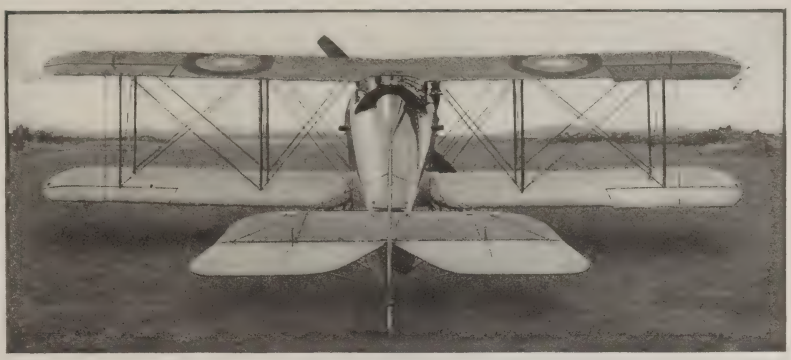
Five Landing Fields

"Further preparations also are being made along the New York-Chicago route. The department has established five landing fields and emergency stops for the 800-odd miles. Leaving Belmont Field, N. Y., the air-mail pilot will have an emergency haven at Lehighton, Pa., 105 miles distant. One hundred and fifteen miles farther he will have a regular stop at Bellefonte, Pa. Across the crest of the mountains, a stage of 87 miles, he will have a safety field at Clarion, Pa."

The Aerial Mail Carriers' View of Rio de Janeiro



THE STANDARD E-1 SINGLE SEATER

THE "E-1" Single Seater built by the Standard Aero Corporation was designed as a secondary training machine. It is provided with either an 80 H.P. Le Rhone or a 104 H.P. Gnome engine, but in either case the dimensions of the machine remain the same. Slight difference in weights and performances result, depending upon which engine is used, so separate lists are given herewith where such differences occur.

The R. A. F. No. 15 wing curve is used. Dihedral, 3%; aspect ratio of both planes, 7; stagger, 13.02". There is no sweepback nor decalage. Wings are set at an angle of 2° to the propeller axis.

When at rest on the ground the axis of proper is 5' 6" above ground, and when the machine is in flying position the axis is 5' 1" above ground.

Maximum diameter of fuselage, 42½"; fineness ratio, 5.

Power Plant

(*Le Rhone*)

The Le Rhone is a nine-cylinder, air-cooled rotary engine developing 80 h.p. at 1,200 r.p.m. and 84 h.p. at 1,290. Bore and stroke, 4 1/16" by 5½".

The carburetor is especially designed for the Le Rhone. Ignition is supplied by a gear-driven, high-tension magneto.

Fuel tank located near center of gravity, has a capacity of 20 gallons. Fuel is consumed at the rate of .725 lbs. per h.p. per hour.

Oil tank, located below fuel tank, has a capacity of 3 gallons. Oil is consumed at the rate of .03 lbs. per h.p. per hour.

(*Gnome*)

The nine-cylinder rotary Gnome, manufactured by the General Vehicle Company, is known as type B-2. At 1,200 r.p.m. it delivers 104 h.p. Bore and stroke, 110 mm. by 150 mm.

Fuel tank has a capacity of 29.5 gallons; rate of consumption, .80 lbs. per h.p. per hour.

Oil tank capacity, 5 gallons; rate of consumption, .20 lbs. per h.p. per hour.

Summary of Performances

(*With Le Rhone Engine*)

Height (*Feet*)	Speed (*M.P.H.*)	Time of Climb	Rate of Climb *Ft. per min.*
Ground	100–103	0 min. 0 sec.	705

Maj. Harold E. Hartney, Air Service, 1st Pursuit Group. For extraordinary heroism in action near Fismes, France, August 13, 1918. Maj. Hartney voluntarily accompanied a reconnaissance patrol. Realizing the importance of the mission, Maj. Hartney took command, and, although five enemy planes repeatedly made attempts to drive them back, he continued into enemy territory, returning later to our lines with important information. The cool judgment and determination displayed by Maj. Hartney furnished an inspiration to all the members of his command. Home address, Mrs. Harold E. Hartney, care of Russell Hartney, Saskatoon, Saskatchewan, Canada.

Second Lieut. Richard Wilson Steele, observer, Air Service, 166th Aero Squadron. For extraordinary heroism in action near Bois D'Barricourt, France, October 23, 1918. While on a bombing raid back of the German lines Lieut. Steele, accompanied by his pilot, was attacked by six German pursuit planes. They were forced to leave the formation in which they were traveling owing to engine trouble; the enemy began riddling their plane with machine gun fire. Lieut. Steele fought them on all sides and is credited by members of the 11th Aero Squadron, who were flying over him several thousand feet, with having brought down one of his opponents. He was wounded twice in the leg and twice in the arm and continued fighting, although each time he was hit he was knocked down into the observer's cockpit. At last, however, only his tail gun was in working condition, the other two having been disabled by bullets, and Lieut. Steele sank unconscious into the cockpit. Home address, William Steele, father, 426 East Euclid Avenue, Oak Park, Illinois.

First Lieut. Hugh L. Fontaine, Air Service, 49th Aero Squadron. The bronze oak leaf is awarded Lieut. Hugh L. Fontaine for extraordinary heroism in action near Champigneulle, France, October 10, 1918. While leading a patrol of three other machines Lieut. Fontaine attacked four enemy planes in the region of Champigneulle. He succeeded in shooting down two of the enemy planes in flames. The first of these he shot down in the initial attack. The second he attacked while it was endeavoring to shoot down one of our planes which had been rendered helpless by the loss of one of its wings. He dived on the attacking plane and shot it down in flames. Home address, Dr. Bryce Fontaine, stepfather, 1839 Overton Park Avenue, Memphis, Tenn.

First Lieut. Raymond P. Dillon, pilot, Air Service, 24th Aero Squadron. For extraordinary heroism in action near Mezieres, France, November 3, 1918. Lieut. Dillon exhibited courage in the course of a long and dangerous photographic and visual reconnaissance in the region of Mezieres with two other planes of the 24th Aero Squadron. Their formation was broken by the attack of ten enemy pursuit planes; five enemy planes attacked Lieut. Dillon and his observer, who succeeded in shooting down two of these out of control. They then had a clear passage to their own lines, but turned back into Germany to assist a friendly plane with several hostile aircraft attacking it. They succeeded in shooting down one more of the enemy. Home address, Claude A. Dillon, brother, 5839 Prairie Avenue, Chicago, Ill.

Second Lieut. John B. Lee, 3d, Air Service, observer, F. A. 24th Aero Squadron. For extraordinary heroism in action near Mezieres, France, November 3, 1918. Lieut. Lee exhibited extreme courage in the course of a long and dangerous photographic and visual reconnaissance in the region of Mezieres with two other planes of the 24th Aero Squadron. Their formation was broken by the attack of ten enemy pursuit planes; five enemy planes attacked Lieut. Lee and his pilot. With remarkable coolness Lieut. Lee succeeded in shooting down two of the planes. They then had a clear passage to their own lines, but turned back into Germany to assist a friendly plane with several hostile aircraft attacking it. They succeeded in shooting down one more of the enemy. Lieut. Lee and pilot returned to our lines with information and photographs of great military value. Home address, John B. Lee, jr., father, 667 Highland Avenue, Newark, N. J.

First Lieut. George A. Goldthwaite, pilot, Air Service, 24th Aero Squadron. For extraordinary heroism in action near the Bois de Bantheville, France, October 15, 1918. In the course of a special reconnaissance to locate a hostile concentration massing for a counterattack in the vicinity of the Bois de Bantheville, Lieut. Goldthwaite and his observer flew generally at an altitude of 400 meters, at times as low as 50 meters, 5 kilometers into the enemy's lines. Antiaircraft guns riddled his plane with bullets, pierced the gasoline tank, and drenched both pilot and observer. He continued on until the

NOMOGRAPHIC CHARTS FOR THE AERIAL PROPELLER

By S. E. SLOCUM, Ph.D.

Professor of Applied Mechanics, University of Cincinnati, Member S. A. E.

IN discussing propeller performance it has been customary to assume that the power absorbed by the propeller varies as N^3D^5, and that the thrust varies as N^2D^4, where N denotes the propeller speed in revolutions per minute or per second, and D is its diameter. These assumptions, however, are only true for an ideal propeller; that is, one which is perfectly rigid and perfectly symmetrical. For a propeller as actually constructed, the law governing power and thrust may differ materially from the above theoretical assumptions. This fact has been shown by the writer in articles appearing in this magazine for August 26 and November 18, 1918. In these articles the actual laws governing propeller thrust and power for a particular propeller were developed directly from experimental data obtained by M. Eiffel and Captain Dorand, without making any theoretical assumptions whatever, the method employed being the standard process for the adjustment of observations by the method of Least Squares. The results showed that the performance of a given propeller may differ materially from that prescribed by theory for an ideal propeller, and also showed how experimental data on propellers may be analyzed on its own merits, independently of all dynamical assumptions.

As long as the whole subject of propeller performance was in the experimental stage, it was doubtless wise to base all calculations on the assumption of an ideal propeller, as it gave a certain uniformity to results. At present, however, when propeller types are becoming standardized, it certainly permits of greater refinement in design to determine by experiment the characteristics of the standard types of propeller adopted. This is the method followed in all lines of engineering. For instance, the performance of aviation motors is determined for a given type of motor by actual test of this type and not solely from the principles of thermodynamics, while as another example, the firing data for a long range gun are based on experiments made on this particular type of gun and not on the ideal assumptions of a perfect projectile fired in vacuo.

Of course it cannot be expected that general formulas for thrust and power can be derived which will apply universally to all types of propellers, any more than that a gas engine power formula can be derived which will apply accurately to all types of motors. It is perfectly possible, however, to derive formulas by the method mentioned above which will apply accurately to a *given type* of propeller, which will assist materially in the problem of powering aircraft, that is, in determining the most effective combination of motor and propeller for a given wing and fuselage assembly.

The formulas so obtained, however, are exponential, and consequently somewhat difficult to use in their algebraic form. To represent graphically the various combinations of quantities involved, M. Eiffel devised what he called "Polar Logarithmic Diagrams," which constitute, in fact, a very ingenious and practical application of vector algebra. But the application as well as the theory of these diagrams, is rather complicated, while the results depend in part at least on determining the intersection of lines which meet at an acute angle, and such points of intersection are liable to a considerable error when determined graphically.

There has recently come into use another means for the graphical solution of exponential formulas which is similar in principle to that devised by M. Eiffel in that it depends on the reduction of an exponential to a linear form by the use of logarithms, and the employment of logarithmic scales. This device consists in the construction of diagrams called nomographic charts, or alignment charts, from which the required results may be obtained by simply connecting the points representing the given data by straight lines, and then reading off the intercepts on the proper scale, the method being similar to that of using a slide rule.

In Plates I and II accompanying this article, nomographic charts are shown which represent the formulas for thrust and power of the aerial propeller as previously derived by the writer in the references given above. These charts, of course, are not universal, as they simply represent the performance of a particular propeller, but similar charts differing only very slightly from these may be constructed for any standard type of propeller, and their use will facilitate calculations on this propeller to the same extent that the use of the ordinary slide rule simplifies arithmetical calculations.

It may be noted that the effect of varying the exponents of N and D will be to move the intersection axes slightly to one side. For instance, if we follow the theoretical assumption that the thrust varies as N^2D^4, the intersection axis on the thrust chart will be moved slightly to the right of the position shown; while similarly on the power chart, the assumption of N^3D^5 will also move the intersection axis slightly to the right. Likewise any change in the quadratic terms involved in these formulas will affect the relative location of the points on the scale giving the ratio $\frac{V}{ND}$, and in this way change the readings on the horsepower and thrust scales. Except for such shifting of the intersection axes and changes in the graduation of the various scales, the nomographic charts will be exactly similar in form for all types of propellers.

Having determined the thrust and power for a given propeller, the torque and efficiency are easily found. Thus

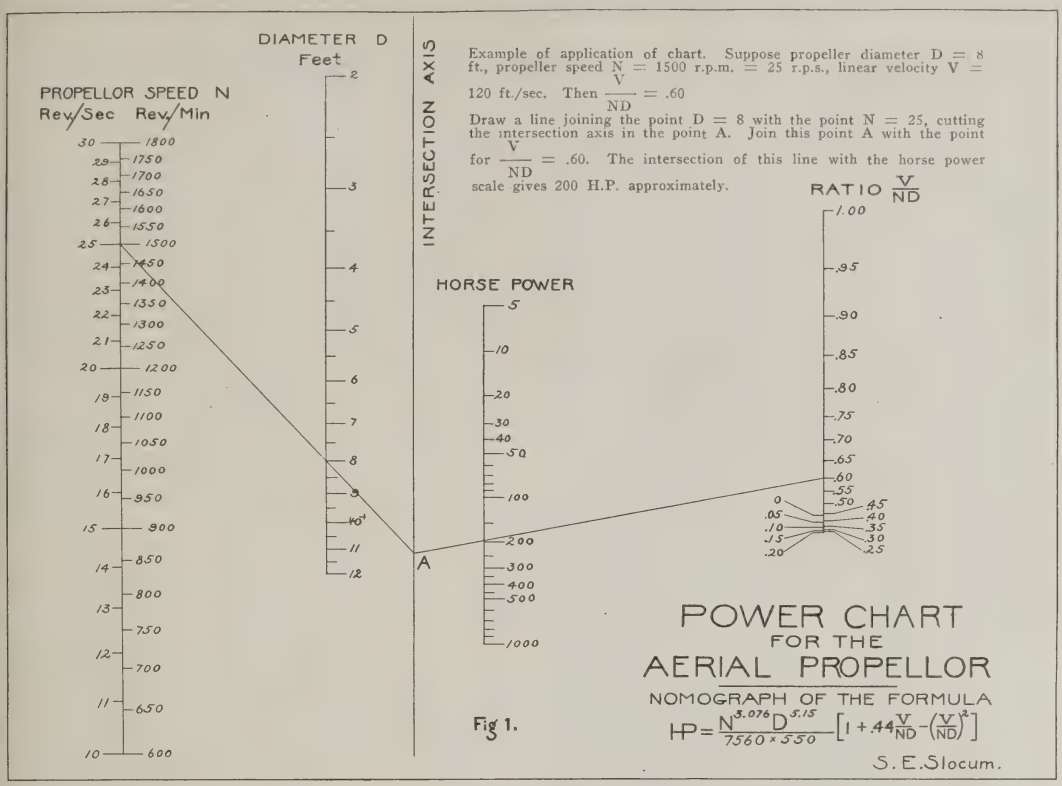
$$\text{Torque} = \frac{\text{H. P.}}{2\pi N}$$

and

$$\text{Efficiency} = \frac{\text{Useful work}}{\text{Total work}} = \frac{F.V.}{550\ \text{H. P.}},$$

where F denotes the propeller thrust, and V is the speed of the plane, or relative velocity of the wind with respect to the propeller. To make the graphical solution complete, however, nomographic charts may also be constructed to give torque and efficiency, as shown on Plate III.

These charts are presented separately in Plates I, II and III for the sake of clearness, and an example of their use is shown on each.



For practical purposes it is more convenient to put all the charts on one sheet, as shown on Plate IV. As an example of its use it may be well to follow through the construction shown on Plate IV. In this example we are given propeller diameter $D = 8$ ft.; propeller speed $N = 1{,}500$ r. p. m. $= 25$ r. p. s.; linear speed $V =$ 90 miles per hour $= 132$ ft. per sec. First join $N = 1{,}500$ with $D = 8$, cutting power axis in A and thrust axis in B. Since $\frac{V}{ND} = .66$, join A with this point on the scale $\frac{V}{ND}$ for power. The intercept of this line with the power scale gives H. P. $= 180$. Next join B with the point .66 on the scale $\frac{V}{ND}$ for thrust. The intercept of this line with the thrust scale gives Thrust $F = 590$ lbs. Now join H. P. $= 180$ with $N = 1{,}500$. The intercept of this line with the torque scale gives Torque $T = 650$ ft. lbs. Lastly, join the point Thrust $F = 590$ with the point $V = 132$ on the velocity scale, cutting the efficiency axis in the point C. Join this point C with the point H. P. $= 180$. The intercept of this line with the efficiency scale gives Efficiency $=$ 76 per cent.

Cited for Distinguished Service

First Lieutenant Ralph P. Bagby, Field Artillery, observer, 88th Aero Squadron. For extraordinary heroism in action near Tailley, France, November 1918. Lieutenant Bagby and First Lieutenant Louis G. Bernheimer, pilot, on their own initiative went on a reconnaissance mission, flying 50 kilometers behind the German lines, securing valuable information as to the condition of the bridges across the Meuse River and enemy activity in the back areas and also harassing enemy troops. Home address, R. J. Bagby, father, New Haven, Mo.

Second Lieutenant John B. Lee, 3d., observer, F. A., 24th Aero Squadron. For extraordinary heroism in action near Mezieres, France, November 3, 1918. Lieutenant Lee exhibited extreme courage in the course of a long and dangerous photographic and visual reconnoissance in the region of Mezieres with two other planes of the 24th Aero Squadron. Their formation was broken by the attack of ten enemy pursuit planes; five enemy planes attacked Lieutenant Lee and his pilot. With remarkable coolness Lieutenant Lee succeeded in shooting down two of the planes. They then had a clear passage to their own lines, but turned back into Germany to assist a friendly plane with several hostile aircraft attacking it. They succeeded in shooting down one more of the enemy. Lieutenant Lee and pilot returned to our lines with information and photographs of great military value. Home address, John B. Lee, Jr., father, 667 Highland Avenue, Newark, N. J.

Second Lieutenant Dogan H. Arthur, pilot, Air Service, 12th Aero Squadron. The bronze oak leaf is awarded Lieutenant Arthur for the following acts of extraordinary heroism in action October 18 and 30, 1918, to be worn on the distinguished service cross awarded him October 3, 1918. On October 18, 1918, while on artillery reglage, Lieutenant Arthur and his observer were attacked by four enemy planes. His observer's guns were jammed, but Lieutenant Arthur, with splendid courage and coolness, outmaneuvered the hostile aircraft and escaped, although they followed his plane to within 25 meters of the ground, badly damaging it by machine-gun fire. On October 30, 1918, Lieutenant Arthur was one of a formation of nine planes which were to take photographs in German territory.

Example of application of chart. Suppose propeller diameter D = 8 ft., propeller speed N = 1500 r.p.m. = 25 r.p.s., linear velocity V = 120 ft./sec. Then $\frac{V}{ND} = .60$

Draw a line joining the point D = 8 with the point N = 25, cutting the intersection axis in the point A. Join this point A with the point for $\frac{V}{ND} = .60$. The intersection of this line with the horse power scale gives 200 H.P. approximately.

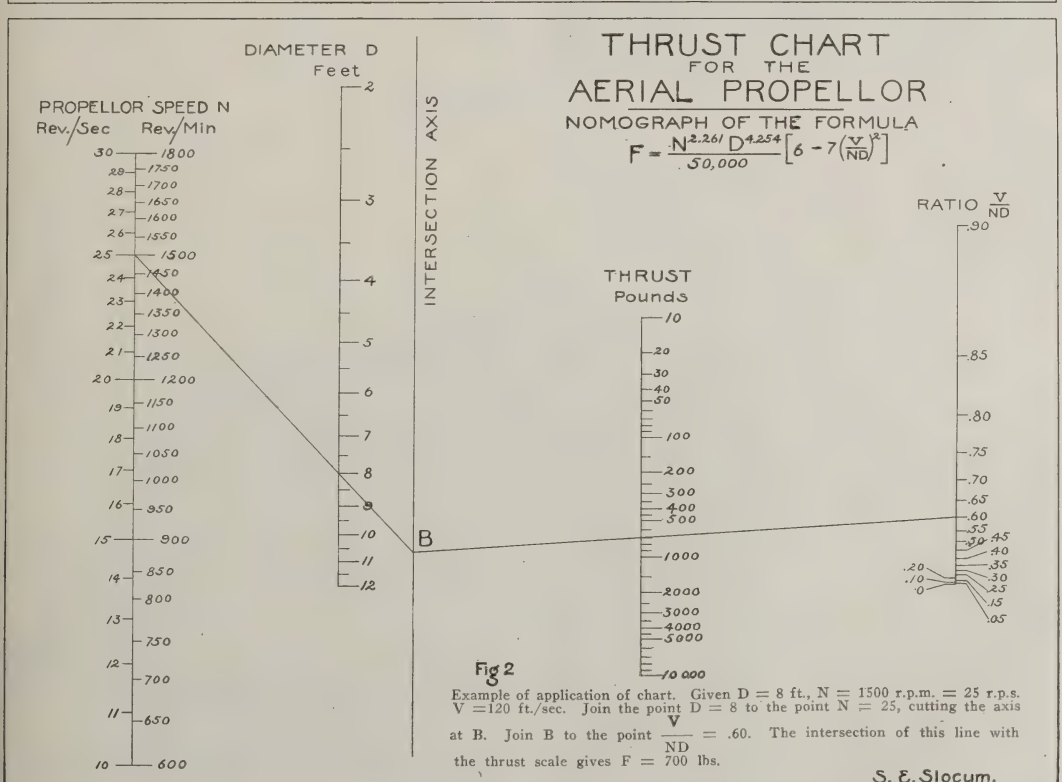


Fig 1.

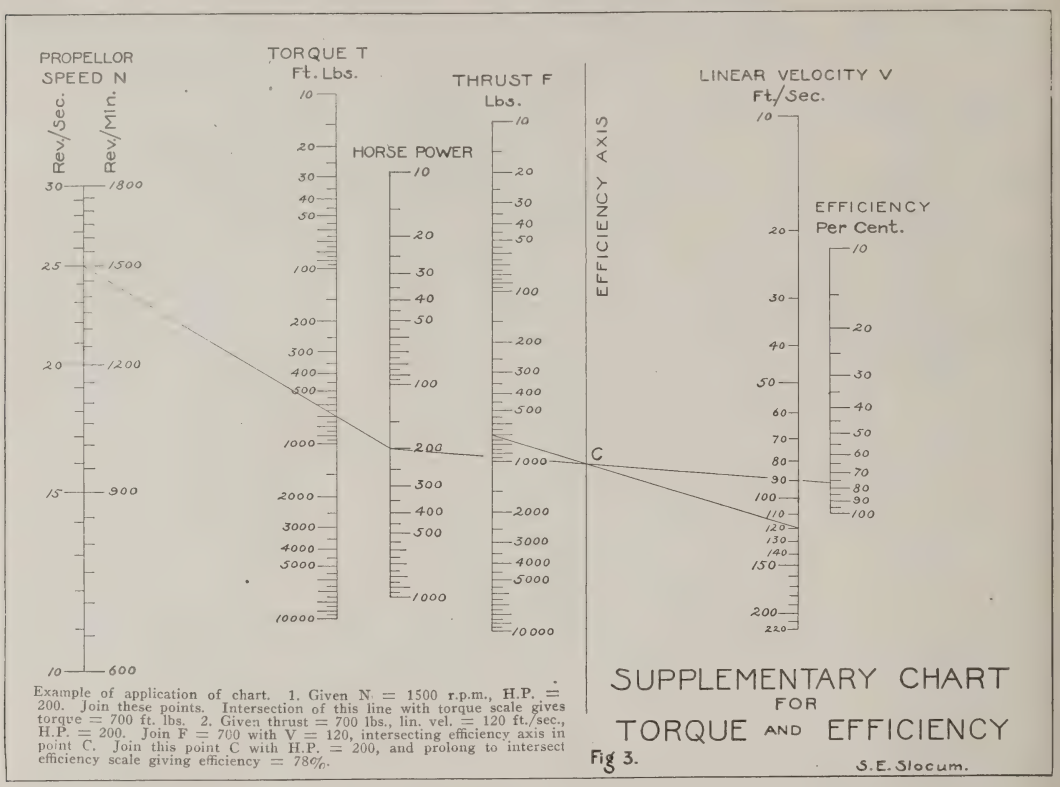
POWER CHART FOR THE AERIAL PROPELLOR

NOMOGRAPH OF THE FORMULA

$$HP = \frac{N^{3.076} D^{5.15}}{7560 \times 550}\left[1 + .44\frac{V}{ND} - \left(\frac{V}{ND}\right)^2\right]$$

S. E. Slocum.

THRUST CHART FOR THE AERIAL PROPELLOR



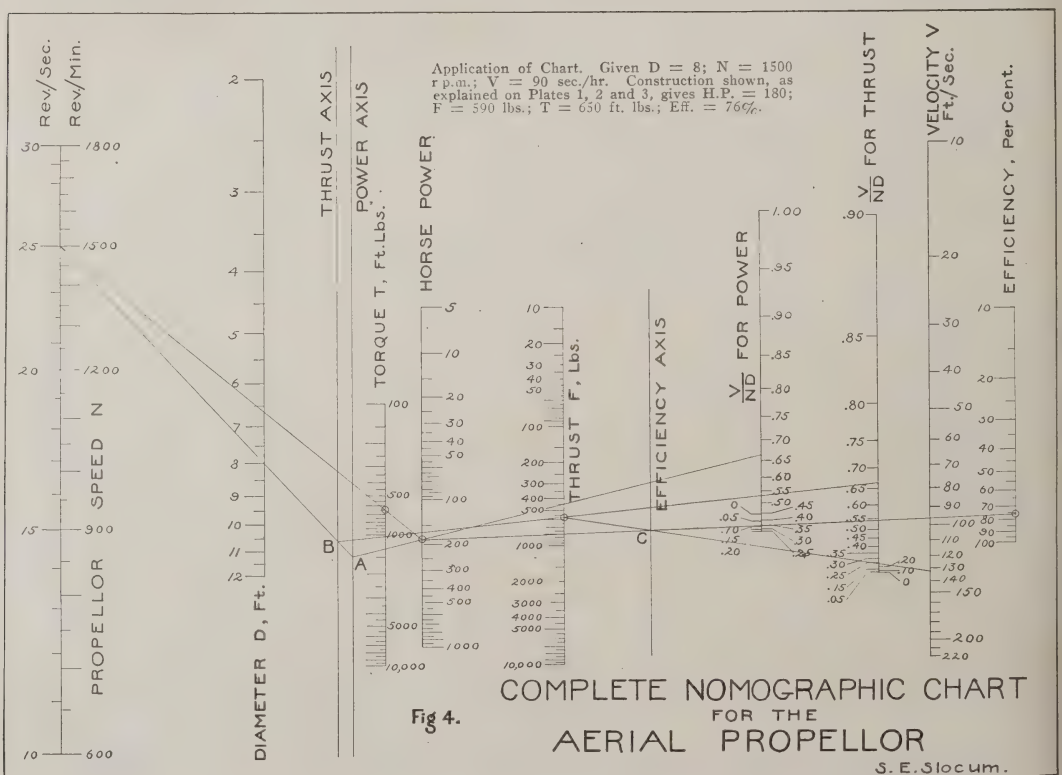
NOMOGRAPH OF THE FORMULA

$$F = \frac{N^{2.261} D^{4.254}}{50{,}000}\left[6 - 7\left(\frac{V}{ND}\right)^2\right]$$

Fig 2

Example of application of chart. Given D = 8 ft., N = 1500 r.p.m. = 25 r.p.s. V = 120 ft./sec. Join the point D = 8 to the point N = 25, cutting the axis at B. Join B to the point $\frac{V}{ND} = .60$. The intersection of this line with the thrust scale gives F = 700 lbs.

S. E. Slocum.



Example of application of chart. 1. Given N. = 1500 r.p.m., H.P. = 200. Join these points. Intersection of this line with torque scale gives torque = 700 ft. lbs. 2. Given thrust = 700 lbs., lin. vel. = 120 ft./sec., H.P. = 200. Join F = 700 with V = 120, intersecting efficiency axis in point C. Join this point C with H.P. = 200, and prolong to intersect efficiency scale giving efficiency = 78%.

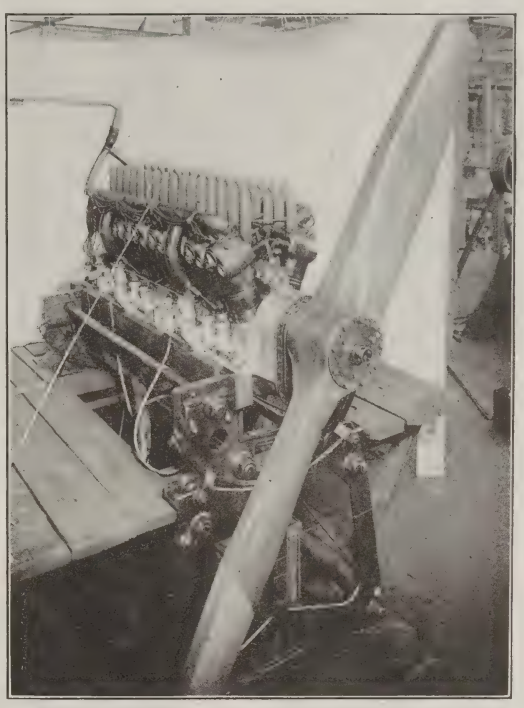
THE DUESENBERG MODEL H 850 H. P. MOTOR

By G. DOUGLAS WARDROP, M. S. A. E., A. S. M. E.

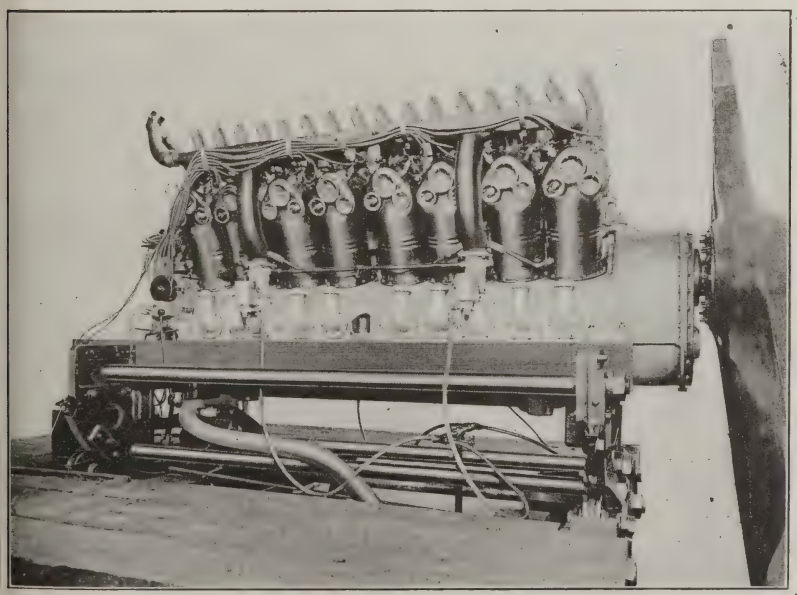
THE Model H Duesenberg motor, developing 850-900 horsepower, built by the Duesenberg Motor Corporation, of Elizabeth, N. J., is the most ambitious aero engine development that has been attempted, and carried through successfully, in the United States. It was designed by F. S. Duesenberg, the pioneer builder of automobile speed engines, and he had the able assistance and cooperation of William Beckman. The motor is of the sixteen cylinder, V type, with the cylinders at an angle of 45°, and the weight of the power plant with gear drive is 1,575 lbs., without gear drive 1,390 lbs.; remarkably low weight ratio for a power plant of its power.

General Data



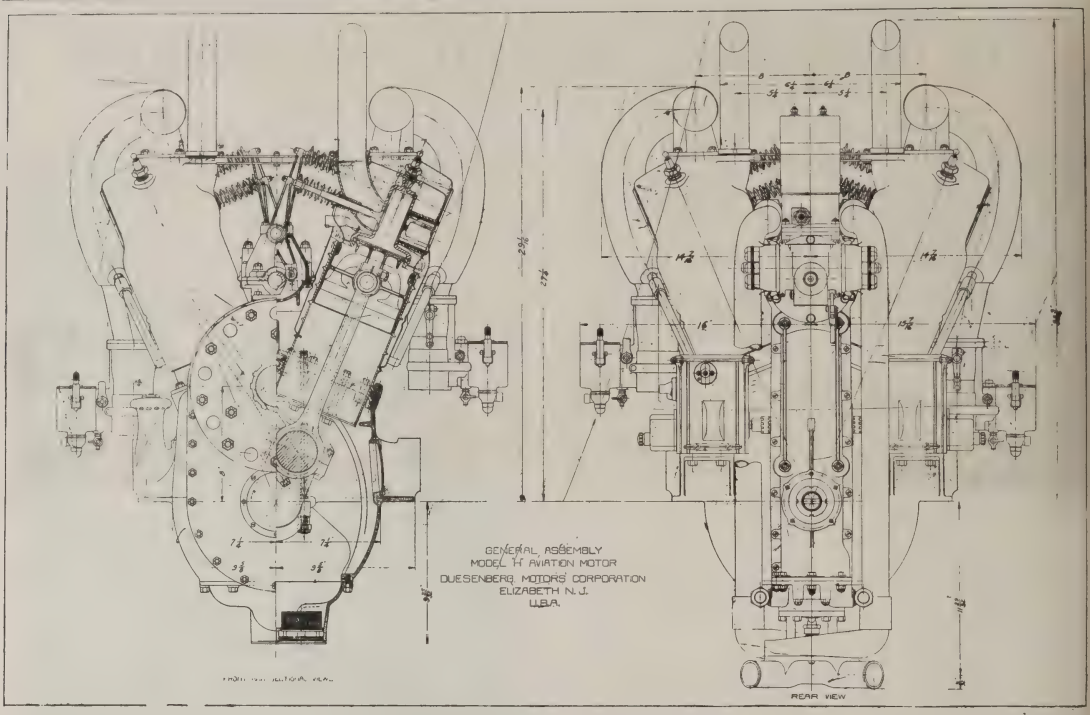
Number and arrangement of cylinders	Sixteen V
Included angle	45°
Bore	6″
Stroke	7½″
Normal Brake Horsepower	800 at 1800 r.p.m.
Type of gear	Overhead camshaft and valve rockers
Number of carburetors	Four Miller

Valves



Number per cylinder	One inlet and two exhaust
Outside diameter	Exhaust 2-3/16″, Inlet 2-5/16″
Port diameter	Exhaust 1-31/32″, Inlet 2-23/32″
Width of seat	7/64″
Angle of seat	30°
Valve lift (inlet)	9/16″
Valve lift (exhaust)	½″
Diameter of stem	Inlet ½″, Exhaust 7/16″
Length of valve	Exhaust 6-27/32″, Inlet 6⅞″
Number of springs per valve	two concentric
Length of springs in position	Outer 2⅞″, Inner 2¾″
Mean diameter of coils (large spring)	1⅛″
Mean diameter of coils (small spring)	1″
Inlet rocker clearance	.010
Exhaust rocker clearance	.015

Cylinders



Overall height of cylinders	19-1/16″
Length of projection in crankcase	2¾″
Diameter of cylinder over waterjacket	6-27/32″ min.
Diameter of cylinder over waterjacket	7-7/32″ max.
Thickness of flange (base)	¼″
Number of studs	9
Thickness of waterjacket	18 gauge
Thickness at cylinder head	7/32″
Thickness of combustion chamber wall	9/64″
Thickness of cylinder barrel	3/32″

Thickness of cylinder pads....½″
Thickness of supporting flange....⅜″
Center distance of motor support bolts....17¼″

Crankcase (Lower)

Material....Aluminum
Thickness of wall....3/16″

Lubrication

Type....Forced Feed
Type of pumps....Rotary Gear
No. of pumps....1 double pressure and 1 scavenging
Ratio of pump speed to chankshaft speed....1 to 1

Ignition

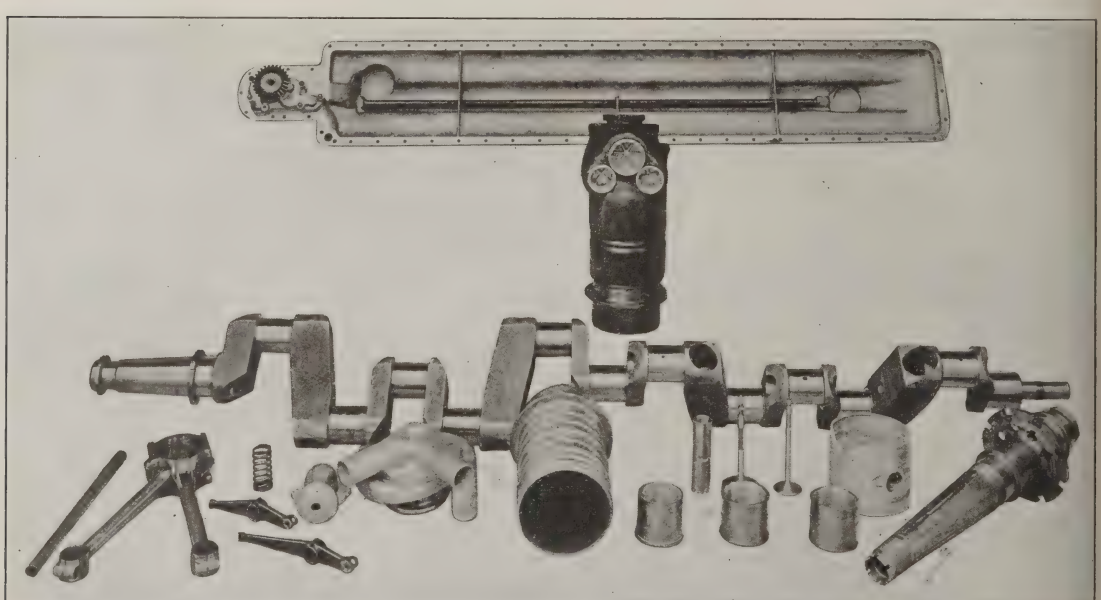
Type....Battery and generator
Firing order....L: 4-8-2-6-1-5-3-7; R: 1-5-3-7-4-8-2-6
Type of plug....A.C.
Ratio of generator speed to crankshaft speed....2 to 1

Cooling System

Type....Water cooled
Pump....1 centrifugal
Diameter of inlet pipe....1⅝″
Diameter of outlet pipe....1⅝″
Number of outlets....2
Diameter of rotor....5¾″
Ratio of pump speed to crankshaft speed....1 to 1
Water temperature inlet....125 F
Water temperature outlet....155 F

The ignition mountings permit of any standard make magnetos being used and recent motors have been equipped with two 8-cylinder Dixie magnetos of fixed spark and Delco special distributor with battery current furnished by Delco and Liberty generator. The Philbrin battery ignition system has been tested on this engine also with very successful results.

In the cooling system the water is delivered from the pump through two 1⅞″ diameter tubes which connect to two headers or manifolds, one along each side and one located directly under the valves near the top of the cylinders. This header is joined to the cylinder by means of the outlet connections. At each cylinder where the water enters is welded a distributor which leads two streams of water, one directly beneath each exhaust port and a third stream to the outside of the cylinder wall or barrel. The water is taken out of the cylinder by means of an opening at the top of the cylinder which



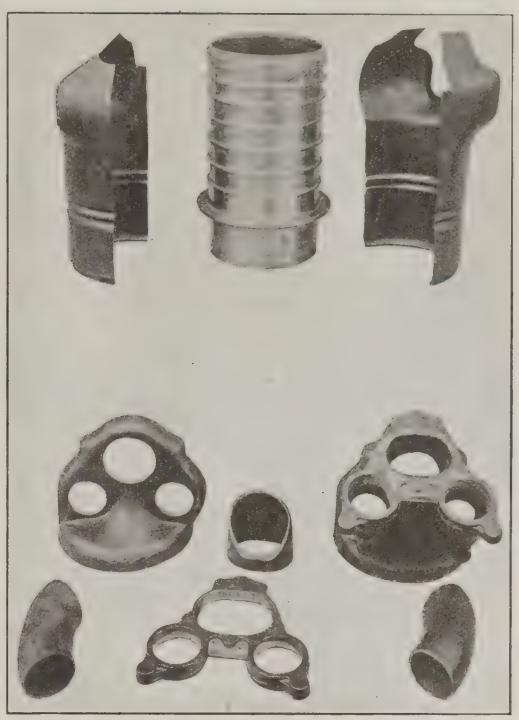


Illustration above shows dry sump oil pan, cylinder, crankshaft, rocker-arm shaft, connecting rod, rocker arms, valve spring, breather tube, water pump, cylinder barrel, bearings, piston pin, valves, and piston

registers with openings and water jacketed gas inlet manifolds; also, a small connection leads the water from the lower part of cylinder jacket to lower portion of water jacket and gas intake manifold. This system permits of a very even temperature, and by tests it has been found that the water pressure is the same at all parts of the motor.

The four Miller carburetors are used, each to feed four cylinders. Two of these carburetors are clamped directly to footings on the crankcase and two are attached to an air duct, which, in turn, is fastened to footings in order to prevent vibration. These footings are of the box girder construction and extend through the width of crankcase and located over each intermediate main crank bearing so that the air to the carburetors is drawn through these footings, which tends to cool the main crank bearings as well as furnish heated air to carburetors.

The rocker arms in the Model H are much shorter than on the normal Duesenberg type. They are of chrome-nickel steel forgings. The camshaft and rocker arm actuating mechanism are entirely enclosed in a dust-proof and oil-proof housing, the oil being fed to both the cams, camshaft bearings and rocker arm shafts under pressure. The rocker arm bearings are of Non-Gran bronze, and the camshaft bearings of babbit lined aluminum.

The oiling system consists of a high pressure and low pressure line operated by a unit of tripe gear pressure and scavenging pumps mounted in the oil pan inside of the crankcase. The high pressure line feeds the crankshaft, connecting rods and thence through a regulating valve to the low pressure line feeding cylinder barrels, cams, camshaft and rocker arms.

The cylinder construction. Barrel of chrome-nickel steel, water jacket of sheet steel, head portion of steel stampings

enemy's concentration was located and military information of great value secured. The bravery of Lieut. Goldthwaite saved the lives of many American soldiers and brought large losses to the enemy. Home address, Mrs. Condace Goldthwaite, mother, Fifth and Garfield Streets, Marion, Ind.

First Lieut. Field E. Kindley, Air Service. In action near Bourlon Wood, France, September 24, 1918. Lieut. Kindley attacked seven hostile planes (type Fokker) and sent one crashing to the ground. A bronze oak leaf is awarded to Lieut. Kindley for the following act in action near Marcoing, France, September 27, 1918. Flying at a low altitude, this officer bombed the railway at Marcoing and drove down an enemy balloon. He then attacked German troops at a low altitude and silenced a hostile machine gun, after which he shot down in flames an enemy plane (type Halberstadt) which had attacked him. Lieut. Kindley has so far destroyed seven enemy aircraft and driven down three out of control. Home address, care of Bank of Gravette, Ark.

Second Lieut. Kenneth L. Porter, Air Service, 147th Aero Squadron. For extraordinary heroism in action near Chateau-Thierry, France, July 2, 1918. Lieut. Porter, with four other pilots attacked 12 enemy aircraft (type Pfalz), flying in two groups well within the enemy lines. As soon as the enemy planes were sighted, Lieut. Porter maneuvered to get between them and the sun and with great difficulty gained the advantage. While three of the other American officers dived on the lower formation, Lieut. Porter and Second Lieut. John H. Stevens engaged the upper formation in a bold and brilliant combat, two planes of which they crashed to the earth. Home address, 105 Green Street, Dowagiac, Mich.

Second Lieut. John H. Stevens, deceased, Air Service, 147th Aero Squadron. For extroadinary heroism in action near Chateau-Thierry, France, July 2, 1918. Lieut. Stevens, with four other pilots, attacked 12 enemy aircraft (type Pfalz) flying in two groups well within the enemy lines. As soon as the enemy planes were sighted, Lieut. Stevens maneuvered to get between them and the sun, and with great difficulty gained the advantage. While three of the other American officers dived on the lower formation, Lieut. Stevens and Second Lieut. Kenneth L. Porter engaged the upper formation in a bold and brilliant combat, two planes of which they crashed to the earth. Home address, Mrs. Effie Stevens, 21 State Street, Albion, N. Y.

Capt. Victor H. Strahm, Air Service, pilot, 91st Aero Squadron. For extraordinary heroism in action near Metz, France, September 13, 1918. Capt. Strahm displayed remarkable courage and skill in penetrating the enemy territory for a distance of 25 kilometers, flying at an altitude of less than 300 meters. His plane was subjected to intense fire from antiaircraft guns in the region of Metz, and he was attacked by a superior number of German planes, one of which he destroyed. He completed his mission and returned with information of great military value. Home address, Frank J. Strahm, Bowling Green, Ky.

First Lieut. Oscar B. Myers, Air Service, 147th Aero Squadron. For extraordinary heroism in action near Cierges, France, September 28, 1918. Sent on a particularly hazardous mission, he harassed and routed enemy troops. Lieut. Myers then climbed higher to look for German planes. With two other officers he encountered nine Fokkers protecting a reconnaissance machine, flying in one of the most effective formations used by the enemy. Outmaneuvering the hostile planes, the three officers succeeded in routing them. After a quick turn Lieut. Myers dived at the reconnaissance machine and crashed it to the ground in flames. Home address, S. Oscar Myers, 109 South Third Avenue, Mount Vernon, N. Y.

First Lieut. William T. Badham, Air Service, observer, 91st Aero Squadron. For extraordinary heroism in action near Nuzancy, France, October 23, 1918. This officer gave proof of exceptional bravery while on a photographic mission 25 kilometers within the enemy lines. His plane was attacked by a formation of thirty enemy aircraft; by skillful work with his machine gun, Lieut. Badham successfully repelled the attack and destroyed two German planes. At the same time he manipulated his camera and obtained photographs of great military value. Home address, H. L. Badham, Whitaker Street, Birmingham, Ala.

First Lieut. George C. Kennedy, Air Service, pilot, 91st Aero Squadron. For extraordinary heroism in action near Jametz, France, October 9, 1918. This officer gave proof of his bravery and devotion to duty when he was attacked by a superior number of aircraft. He accepted combat, destroyed one plane and drove the others off. Notwithstanding that the enemy returned and attacked again in strong numbers. Lieut. Kennedy continued his mission and enabled his observer to secure information of great military value. Home address, L. Gordon Glazier, 4 Egremont Road, Boston, Mass.

First Lieut. Benjamin L. Atwater, Air Service, observer, 99th Aero Squadron. For extraordinary heroism in action near Landres-A-St. Georges, France, October 5, 1918. Lieut. Atwater started on a photographic mission with Lieut. Alexander, pilot, over the enemy's lines. Forced back by seven enemy pursuit planes, he determined to complete his mission, and recrossed the lines eight minutes later. A large group of enemy pursuit machines again attacked his plane. Disregarding his wound, he operated his machine gun with such effect that the nearest of the enemy planes was put down out of control. Home address, Mrs. Ella Atwater, mother, 152 Maple Avenue, Red Bank, N. J.

Second Lieut. William J. Brotherton, Air Service, 147th Aero Squadron. For extraordinary heroism in action near Fere-En-Tardonois, France, on August 1, 1918. An enemy Rumpler plane being reported over the aerodrome, Lieut. Brotherton with another officer ascended and soon encountered six Fokker planes that were protecting another Fokker serving as a decoy. Disregarding the enemy's superiority in numbers, he maneuvered so as to secure the advantage of the sun and dived on the decoy plane; pouring in a destructive fire, he killed the pilot and crashed the machine to the ground. Home address, C. J. Brotherton, Guthrie, Ill.

First Lieut. Lansing C. Holden, Air Service, 1st Pursuit Group. For extraordinary heroism in action near Montigny, France, October 23, 1918. Lieut. Holden was ordered to attack several German balloons, reported to be regulating effective artillery fire on our troops. After driving off an enemy plane, encountered before reaching the balloons, he soon came upon five balloons in ascension 1 kilometer apart. In attacking the first, which proved to be a decoy with a basket, his guns jammed; after clearing them he attacked the second balloon, forcing the observer to jump. His guns again jammed before he could set fire to this balloon. Moving on the third balloon at a height of only 50 meters, he set fire to it and compelled the observer to jump. He was prevented from attacking the two remaining balloons by the further jamming of his machine guns. Home address, L. C. Holden, father, 888 West End Avenue, New York, N. Y.

(Continued from page 980)

In response to this Mr. Deeds received from Mr. Coffin this telegram on the following day:

"1917 May 10 PM 8:56

Darien, Ga.
E. A. DEEDS,
New Willard Hotel, Washington, D. C.
Do not hesitate for reasons given. Want your advice and membership on board be sure and be on hand for Tuesday and Wednesday next as I desire Board to put up strong program to council on these dates See you Tuesday morning

HOWARD E. COFFIN."

This was followed by a telegram from Mr. Deeds in the following language:

"Washington, D. C.
May 11, 1917.

HOWARD E. COFFIN,
Darien, Georgia.

Will accept membership on the board and be on hand Tuesday and Wednesday.

E. A. DEEDS.

Under date of May 17, Mr. Coffin sent to Mr. Deeds a letter in the words and figures as follows:
"DEAR MR. DEEDS:
On April 12th, 1917, the following resolution was passed by the Council of National Defense:
'That Commissioner Coffin be asked to take the Chairmanship of an Aircraft Production Board, as outlined in letter of April 10, 1917, of Dr. C. D. Walcott, Chairman Executive Committee, National Advisory Committee on Aeronautics, the personnel of which he shall select
'The National Advisory Committee for Aeronautics have the honor to recommend to the Council of National Defense that a Board be appointed by the Council of National Defense, to be known as the Aircraft Production Board.
'The function of this Board shall be to consider the situation in relation to the quantity production of aircraft in the United States, and to cooperate with the officers of the Army and Navy, and of other Departments interested in the production and delivery to these Departments of the needed aircraft in accordance with the requirements of each Department.'
In accordance with this resolution I desire to ask you to serve as a member of the Aircraft Production Board. The names of the other members who will constitute the personnel of the Board are as follows:

Brig. General George O. Squier, C. S. O.
Rear Admiral Taylor, Bureau of Construction,
Mr. S. D. Waldon
Mr. R. L. Montgomery

and such other additional appointments as future developments may make necessary or desirable.
I trust I have your acceptance,

Very truly yours,
(Signed) H. E. COFFIN.

Mr. E. A. Deeds,
Room 527, Munsey Building,
Washington, D. C."

Mr. Deeds accepted the appointment so tendered him and served on the Aircraft Production Board until August 2, 1917, when he was appointed acting chief of the equipment division of the Signal Corps, at a salary of $1 per year.

On August 24, 1917, Mr. Deeds received a letter from the Adjutant General of the Army informing him that the President of the United States had appointed him temporarily a Colonel in the Signal Corps in the Regular Army of the United States, to rank as such from the 15th day of August, 1917, and instructing him immediately upon receipt of the communication, to return the oath of office properly filled in, subscribed and attested. He accepted this appointment on August 27th, 1917. Before doing so, however, he called upon the Secretary of War and stated very frankly what his business connections were and suggested that if he accepted the commission, he might be criticized, and asked advice from the Secretary of War. He then sent for his attorney, Judge McCann, of Dayton, Ohio, who came to Washington and advised Mr. Deeds what he ought to do with reference to his various activities. This advice was solicited by Mr. Deeds because, to use his own words, he did not "want to do anything that would not be in strict accordance with the law." He left the matter in the hands of his attorney "to finish up." He took immediate steps to sever his connection with the various corporations with which he was affiliated, and on August 28th signed and sent to the Aircraft Production Board and to the Secretary of War letters which had been prepared by his attorney and which were as follows:

"August 28, 1917.

HON. NEWTON D. BAKER,
Secretary of War,
Washington, D. C.
SIR:

You have honored me by appointment temporarily as an Officer in the Regular Army of the United States, and as a member of the Aircraft Production Board connected with your Department. It is possible that that this Board in the development of the aeroplane work may wish to recommend a contract with some of the corporations in which I have had an interest. Following the advice of counsel, I have resigned my official relations with these corporations, and made bona fide transfers of my stock therein to other parties.
For your protection as well as my own, I desire to file with your department a copy of a written disclosure of my relations, both past and present, to these corporations which I have this day filed with the Aircraft Production Board, and I enclose same herewith.
In serving in the positions to which you have appointed me, I desire to comply with both the spirit and letter of the law, and to do no act which might invite criticism upon myself or your department.
I count it an honor and privilege to be thus called into the service of our country, and am pleased to make whatever sacrifice of time and money that service may demand.
I enclose an extra copy of my statement to be filed with you as Chairman of the Council of National Defense.

Yours very respectfully,
(Signed) E. A. DEEDS.

"THE AIRCRAFT PRODUCTION BOARD,
Munsey Building,
Washington, D. C.
GENTLEMEN:

As a member of your Board and interested in the letting of contracts on the recommendation of that Board on behalf of the Government, I desire at this time to make a full and complete disclosure of the interest I may have in any corporation which might be a party to any such contract, or which might furnish supplies to the Government through the instrumentalities of your board.

I was a stockolder and officer in the following, to wit:

1. The United Motors Corporation of New York, being a union of several companies manufacturing automobile parts.

2. The Dayton Engineering Laboratories Company, of Dayton, Ohio, manufacturing ignition and starting devices for automobiles.

3. The Dayton Metal Products Company, of Dayton, Ohio, engaged among other things, in the manufacture of munitions.

4. The Domestic Building Company, of Dayton, Ohio, a corporation formed for the development of real estate and which now owns the land and buildings leased to the Dayton Wright Airplane Company.

In all of the foregoing corporations I have severed my official connection therewith by resignation and have made a bonafide transfer to other parties of all my stock therein.
In addition to the above corporations, I was an incorporator of the Dayton Wright Airplane Company, but never owned any stock therein. I am also President of and a large stockholder in the Domestic Engineering Company, of Dayton, Ohio, makers of Delco Light Plants, and expect to retain my official connection therewith and my financial interest therein.
I also own the ground embraced in the Moraine Experimental Flying Field.
I make this disclosure now so that your Board, as the representative of the Government, may be fully informed as to my relations, past and present, with these corporations, and be thus enabled to act wisely on any order or contract involving any of those corporations either directly or indirectly. I desire that this written disclosure be recorded in the minutes of your Board for the mutual protection of all of us.

Yours very respectfully,
(Signed) E. A. DEEDS."

In response to above written to the Secretary of War Col. Deeds received the following:

"September 2, 1917.

MY DEAR COLONEL DEEDS:

I have received your letter of August 28th and have directed to be filed in the office of the Assistant and Chief Clerk of this Department the statement submitted by you as to your connection in business which might be in some way concerned in the matter of aircraft production. I feel very sure that this statement and your own wise discretion and good judgment will save us from any embarrassment in the matter, but I cannot send this letter, a mere acknowledgment, without adding to it a word of grateful appreciation for the splendid service which you are rendering the Government, and particularly the War Department. I think it is safe to say that neither our Government nor any other has ever had from its citizens service of more distinguished effectiveness or fineness of spirit than is being rendered by you and your associates in the Aircraft Production Board.

Cordially yours,
NEWTON D. BAKER, Secretary of War.

Col. E. A. Deeds, Aircraft Production Board,
Munsey Bldg., Washington, D. C."

5. The former memorandum from this office based entirely upon the report submitted by Judge Hughes recommended court-martial proceedings against Colonel Deeds by reason of the transactions to which reference will now be made.

I

Telegram Dated September 16, 1917

The telegram referred to was sent by Colonel Deeds from Old Point, Va., to H. E. Talbott at Dayton, Ohio. This is the same Talbott who has been hereinbefore referred to as a former business associate and close friend of Colonel Deeds. At the time the telegram was sent, Mr. Talbott was president of the Dayton Metal Products Company, which owned the stock in the Dayton Wright Airplane Company of which Talbott was also an officer. A contract between the Government and the Dayton Wright Airplane Company for the construction of 3,900 aeroplanes was then in process of negotiation. The telegram is in the following language:

"For your personal information as coming from your local attorney, Judge Advocate General has ruled it legal for government to select one, contractor one, and the two a third, as appraisers of market value of plant at expiration of contract. If you care to raise the question the above will be found to be the final ruling."

Judge Hughes in his report of the Aircraft Inquiry sets forth the above telegram immediately after two telegrams dated August 4, one from Kettering (also a former business associate of Deeds and largely interested in the Dayton Wright Airplane Company) addressed to Deeds, and the other from Deeds to Kettering. The two telegrams are as follows:

"Dayton, Ohio, August 4, 1917.

E. A. DEEDS,
Room 527 Munsey Building,
Washington, D. C.

We believe all confidential telegrams should be sent to Mr. H. E. Talbott, Sr., City National Bank Building, or George B. Smith, instead of the Dayton Wright Airplane Company.

C. F. KETTERING."

"August 4, 1917.

MR. C. F. KETTERING,
City National Bank Building,
Dayton, Ohio.

Hereafter all confidential telegrams will be sent to H. E. Talbott, Sr., instead of the Dayton Wright Airplane Company.

E. A. DEEDS."

These two telegrams should be considered in connection with other telegrams not set forth in Judge Hughes' report, but which were introduced in evidence in the Aircraft Inquiry.
The request from Kettering to Deeds contained in the first telegram of August 4 hereinabove quoted was caused by the receipt at the office of the Dayton Wright Airplane Company of the following telegram dated August 3, 1917:

"August 3, 1917.

DAYTON WRIGHT AIRPLANE COMPANY,
Dayton, Ohio.

The machine about which we talked with Mr. Talbott today will be

expressed to Dayton Monday. This must be placed under strictest guard and under no conditions are any visitors to be permitted to see it. Between the time the machine starts and while the machine is in transit please see that your laboratory is so organized that it is under as thorough control as though it were strictly a military research station. This goes far beyond anything that has been done by your organization before, but must be started vigorously and continually maintained. No one outside of Government officials must know where this machine is.

DEEDS—AIRCRAFT PRODUCTION BOARD.

Charge—Aircraft Production Board."

At that time, as is well known, there was great anxiety not only among the various Government officials, but also among private individuals in all parts of the country, especially those connected with plants which were engaged on Government contracts, concerning the activities of German agents in this country. When the telegram of August 3d, above quoted, was received at the office of the Dayton Wright Airplane Company, it was opened by some one connected with the office force, its contents became known, and it was a subject of some discussion among the employees of the company. That company then had several offices, one in the City National Bank Building in Dayton and another at the factory, and there was uncertainty where telegrams would be delivered, which uncertainty would be obviated by addressing telegrams to Mr. Talbott, at the City National Bank Building. For this reason, Mr. Kettering sent the telegram of August 4th. This was followed the next day by the two telegrams of August 4th quoted by Judge Hughes in his report and noted in his memorandum. These two telegrams of August 4 were followed by three telegrams dated respectively August 6, August 13 and August 14, which were in the following language:

"(DeVine Ex 47) (7/12/18)
August 6, 1917.

MR. H. E. TALBOTT, SR.,
City National Bank Building,
Dayton, Ohio.

Plane will be shipped this afternoon or tomorrow. Will advise particulars later.

DEEDS—Equipment Division, S. C.

Charge—Equipment Division, S. C. (Confirming tele, this date).

"(DeVine Ex 49) (7/12/18)

Washington, Aug. 13, 1917."

"MR. H. E. TALBOTT, SR.,
City National Bank Building,
Dayton, Ohio.

Am sending D. H. four drawings by personal messenger on six ten train tonight. Have him met at train this is the only set of drawings in existence arrange special safe to make their safety absolute also when duplicating the D H four at the laboratory make special provision for fire protection by extra watchman and fire extinguishers after you have the drawing work started will send officer from plane design division to assist messenger will also bring standard tracing sheets to be used making D H four drawings so that they will fit into our Standard Government regulations.

DEEDS—Equipment Division."

"(Sherer Ex 38) (7/11/18)
Dayton, Ohio, Aug. 14, 1917.

E. A. DEEDS,
Aircraft Production Board,
Washington, D. C.

Your wire received will be governed accordingly. Plane not yet received.

TALBOTT—Dayton Wright."

A perusal of these telegrams as a series clearly indicates a very proper degree of solicitude on the part of Colonel Deeds zealously to protect the best interests of the Government and negatives the implication raised by Judge Hughes' report that it was the purpose of Colonel Deeds and Mr. Kettering by the telegrams of August 4th to establish improper secrecy in communications passing between them relating to matters in which the Government was concerned.

The history of the transaction calling forth the telegram of September 16th which was adversely criticized by Judge Hughes, is as follows: When negotiations were first entered into between the Government and private manufacturers looking to the production of aeroplanes, a number of serious obstacles stood in the way of concluding the contracts, one of the most important of which was the question of an allowance for depreciation to cover shrinkage in facilities which the manufacturers would be obliged specially to provide. They realized that this shrinkage was something that could not be absorbed in the profits under the contracts. Among those to whom these obstacles appeared most serious were the Curtiss Manufacturing Company and the Dayton Wright Airplane Company. A basis of adjustment had been suggested, as a result of which the Signal Corps adopted the policy of allowing the constructors, at the completion of their respective contracts, amounts of money equal to the difference between the actual cost of the facilities specially provided, and the fair value of these facilities at the completion of the work, these amounts to be fixed by appraisement. The question was then raised as to how the appraisement should be made. There seemed to be an impression prevalent at the time among certain Army officers that the principle which prevented the government from settling disputes by arbitration, negatived its power to allow appraisements to be made either wholly or partially by those unconnected with the Government. Some of the manufacturers insisted that they be allowed to nominate arpraisers to act in conjuction with the Government apparaisers. It was then decided to submit the question to the Judge Advocate General of the Army. Mr. Montgomery, chief of the consulting department, stated the question to the Acting Judge Advocate General, who orally confirmed Mr. Montgomery's opinion that it would not be illegal to permit the manufacturers to nominate appraisers to act in conjunction with those nominated by the Government. The next day, Mr. Morgan, of the Curtiss Company, was notified, at a meeting of the Aircraft Production Board, of the views of the Acting Judge Advocate General and a contract with the Curtiss Company followed a few days later. The minutes of the Aircraft Production Board show that this meeting occurred on September 14, 1917. The oral opinion given by the Acting Judge Advocate General was confirmed by his letter dated September 19, 1917. Thus it appears that Mr. Morgan, of the Curtiss Company, was advised of this decision of the Acting Judge Advocate General two days before Mr. Deeds communicated it to Mr. Talbott. This is evident from the fact that the telegram to Mr. Talbott was not sent until the 16th of September. It is therefore clear that there was nothing of a confidential character in the information conveyed in Colonel Deed's telegram. Mr. Morgan, of the Curtiss Company, had been advised of these facts at the meeting of the Aircraft Production Board two days before. Such opinions of the Judge Advocate General are as much of a public nature as are the opinions of the Attorney General of the United States. The telegram appears to have been sent in order to expedite the closing of the contract betwees the Government and the Dayton Wright Airplane Company, a contract which, although dated September 7, 1917, was not actually signed and delivered until October 1st. That it was closed after the opinion of the Acting Judge Advocate General above referred to, is shown by the fact that it contains a clause providing for appraisement in accordance with his opinion. Reading the closing of the contract, production was naturally delayed, and it was advisable from the standpoint of the Government that the Dayton Wright Airplane Company be advised that the differences standing in the way of the final consummation of the contract had been removed.

Why Colonel Deeds, in his telegram, used the language, "as coming from your local attorney," is difficult to understand. The fact probably is that he felt that it would be wiser that Mr. Talbott, in discussing the subject with his associates should not use Colonel Deed's name. As there was nothing confidential in the telegram, there seems to be no reason why the name of Colonel Deeds could not properly have been used, as the source of the information conveyed by it. Colonel Deeds was not the Attorney for the Dayton Wright Airplane Company and is not even at attorney at law. The language, therefore, could not be construed as intended to refer to him as occupying any such relation to the company.

Colonel Deeds' explanation of this phrase is given in this language in the affidavit submitted by him:

> "Deeds' idea was to put the information in such a way that it would not look to Talbott like a proposition from the Aircraft Production Board. The application of the ruling of the Judge Advocate General would obviate the principal objection upon which Talbott was insisting. The idea was to impress upon Talbott the prospect of obviating that objection by further negotiation, through his local attorney at Dayton, who was Charles L. Craighead. Deeds was not acting as attorney or confidential advisor of Talbott, nor was he such attorney or confidential advisor. The purpose was to get Talbott to sign up the Dayton Wright contract which is referred to (P. 29) as dated September 7, 1917, but which, as Montgomery says, was not signed until after October 1, 1917. Production was being held up by delay in signing the contract."

From this explanation it appears that while Colonel Deed's real endeavor was to aid the Government in expediting its program of aircraft production, through some mistaken notion he deemed it proper to accomplish that object by a species of deceit which would result in concealment of the source of the information which the telegram conveyed. This was not only foolish, but provocative of the severe criticism which has been visited upon him and in a manner unjustly.

Upon the evidence now before this office, however, court martial proceedings against Colonel Deeds, based upon this transaction, are not advised, (1) No fraud against the government, nor disclosure of confidential information was intended; (2) None was accomplished; (3) The purpose of the telegram was to expedite the earnest efforts which the government officials were making to speed up aeroplane production.

II

Statement Regarding Transfer of Stock in United Motors Co.

Judge Hughes, in his report, finds that on August 28, 1917, when the letters to the Secretary of War and the Aircraft Production Board, above quoted, were written, Colonel Deeds was the owner of 17,000 shares of the capital stock of the United Motors Company, one of the companies mentioned in the letter to the Aircraft Production Board, and of an interest in a pool of certain shares of the stock of that Company, on which 3,880 additional shares were received in November, 1917. He further finds that the only transfer made by Colonel Deeds of any of his shares in that company was by gift to his wife; that he endorsed for transfer the certificates for 17,500 shares on October 13, 1917, and that they were transferred to Mrs. Deeds' name on October 17, 1917. Thereafter these shares of stock were held by George B. Smith, the confidential agent of Colonel Deeds, for Mrs. Deeds' account. It is further found that entries of the transfers were made in Col. Deeds' books by Smith not earlier than October 17, 1917, and were dated back to August 28, 1917; also in the statement of his assets on August 31, 1917, submitted to him by Smith, the shares appeared as part of his property; that Mrs. Deeds' name first appeared in the statement of assets on October 31, 1917. It is further found that the remaining shares (3,880) received on the dissolution of the pool about November 22, 1917, were transferred from the pool manager directly to Mrs. Deeds, as Col. Deeds' donee, and that the certificates were received by Mr. Smith on her behalf; that prior to the transfer of the stock in October, and at the time of Col. Deeds' letter to the Aircraft Production Board, he had simply told his wife that it was to be her stock, but that it does not appear that there had been an effective gift of the shares. The actual value of the 21,380 shares is found to be approximately $500,000.

It must be remembered that at the time Mr. Deeds received his commission he was in Washington and not in Dayton where his business interests were located. It is obvious that all persons connected with aircraft production in Washington in the summer of 1917 were overwhelmed with work. Col. Deeds could not reasonably have been expected to attend to the details of the stock transfers himself and did not attempt to do so. Nor could it reasonably be expected that he would be required to force upon the market stock worth approximately $500,000, to be disposed of, as would inevitably have been the case, at a sacrifice. It does appear from the testimony taken before Judge Hughes, however, that he did offer for sale his stock in the Dayton Metal Products Co., but apparently without result. It is equally clear that Col. Deeds could not be expected to make a gift of this stock to a stranger. What he testified before Judge Hughes he actually did was to give the stock to his wife. It would undoubtedly have been more frank had he disclosed in his letter that he had given the stock to his wife instead of using the language that he had "made a bona fide transfer to other parties" of his stock. Notwithstanding the fact that the gift was to his wife, it may nevertheless have been intended as a bona fide transfer. His original reluctance to accept service under the Government based upon possible conflicting interests (notwithstanding the pressure brought to bear upon him to do so) evidenced by his telegram to Mr. Coffin and by his subsequent voluntary verbal and written disclosure to the Secretary of War and to the Aircraft Production Board of his business relations, is inconsistent with the thought that he was intentionally guilty of lack of frankness.

As bearing upon his attitude throughout, the subsequent actions of Col. Deeds when the Government had under consideration the acquisition of the tract of land owned by the Moraine Development Co., adjoining the factory of the Dayton Wright Airplane Co., for use as a testing field, may well be considered. Col. Deeds was the owner of approximately 25% of the stock of this development company. The Government believed it to be essential that this field be acquired. Col. Deeds found his

CSO—Report to the Chief Signal Officer, Washington, D. C.
CUI—Report to School of Military Aeronautics, Cornell University, Ithaca, N. Y.
CWT—Report to Call Field, Wichita Falls, Texas
DAF—Report to Dorr Field, Arcadia, Fla.
DAP—Report to Director of Aircraft Production, Washington, D. C.
DIK—Report to Camp Dick, Dallas, Tex.
DIS—Honorably discharged from service.
DMA—Report to Director of MilitaryAeronautics, Washington, D. C.
ELA—Report to Eberts Field, Loanoke, Ark.
EOT—Report to Ellington Field, Olcott, Texas.
FLA—Commissioned as First Lieutenant Air Service, National Army.
FLR—Commissioned as First Lieutenant, Aviation Section, Signal Reserve Corps.
FLT—Commissioned as First Lieutenant, Aviation Section, Signal Corps.
FOB—Report to Fort Omaha Balloon School, Omaha, Neb.
FRF—On duty requiring regular and frequent aerial flights.
FSO—Report to Fort Sill School for Aerial Observers, Fort Sill, Okla.
GIT—Report to School of Military Aeronautics, Georgia Institute of Technology, Augusta, Ga.
GLC—Report to Gerstner Field, Lake Charles, La.
HHN—Report to Hazelhurst Field, Mineola, L. I., N. Y.
JMA—Rated as Junior Military Aviator.
JRC—Report to Jackson Field, Riverside, Cal.
KST—Report to Kelly Field, So. San Antonio, Tex. (When specified in the order, the number of the field is given in parentheses)
LDT—Report to Love Field, Dallas, Tex.
LHV—Report to Langley Field, Hampton, Va.
MAC—Report to March Field, Allesandro, Cal.
MAJ—Commissioned as Major, Aviation Section, Signal Corps.
MAT—Report to Mather Field, Sacramento, Cal.
MDO—Report to McCook Field, Dayton, Ohio.
MIA—Report to U. S. Naval Air Station, Miami, Fla.
MIT—Report to School of Military Aeronautics, Massachusetts Institute of Technology, Boston, Mass.
MJA—Commissioned as Major Air Service, National Army.
MJR—Commissioned as Major, Aviation Section, Signal Reserve Corps.
MSC—Report to Radio School, Maryland State Agricultural College, College Park, Md.
OBS—Attached to the Aeronautical Service as Observers.
OSU—Report to School of Military Aeronautics, Ohio State University, Columbus, Ohio.
PFO—Report to Post Field, Fort Sill, Okla.
PMT—Report to Park Field, Millington, Tenn.
PUP—Report to School of Military Aeronautics, Princeton University, Princeton, N. J.
PWM—Report to Payne Field, West Point, Miss.
REL—Relieved from present duty.
RSD—Report to Rockwell Field, San Diego, Cal.
RTR—Retransferred to organization attached to previous assignment to aviation duty.
RWT—Report to Rich Field, Waco, Tex.
SBI—Report to Scott Field, Belleville, Ill.
SAG—Report to Souther Field, Americus, Ga.
SGS—Report to Camp Sevier, Greenville, S. C.
SLA—Commissioned as Second Lieutenant Air Service, National Army.
SLR—Commissioned as Second Lieutenant, Aviation Section, Signal Reserve Corps.
SLT—Commissioned as Second Lieutenant, Aviation Section, Signal Corps.
SMA—Report to School of Military Aeronautics, Cambridge, Mass.
SMM—Report to Selfridge Field, Mount Clemens, Mich.
SRC—Report to Columbia School for Radio Officers, New York City.
TFT—Report to Taliaferro Field, Fort Worth, Texas. (When specified in the order, the number of the field is given in parentheses)
TMA—Report to Taylor Field, Montgomery, Ala.
UCB—Report to School of Military Aeronautics, University of California, Berkeley, Cal.
UIU—Report to School of Military Aeronautics, University of Illinois, Urbana, Ill.
UTA—Report to School of Military Aeronautics, University of Texas, Austin, Tex.
VBW—Report to Vancouver Barracks, Washington.
WAC—Report to Aviation Concentration Camp, Waco, Tex.
WCS—Wire to the Chief Signal Officer upon arrival.
WDM—Wire, Director of Military Aeronautics, upon arrival.
WFO—Report to Wilbur Wright Field, Fairfield, Ohio.

Notes

Note 1—Report to places mentioned in the order named.

Note 2—Report to Aviation General Supply Depot, Middletown, Pa.

Note 3—Report to Aviation General Supply Depot, Little Rock, Arkansas.

Note 4—Report to Dist. Mgr., Aircraft Finance, Consumers, Building, Chicago, Illinois.

Note 5—Report to Army Balloon School, Los Angeles County, California, to commanding officer for duty.

Note 6—Report to Dist. Mgr., Aircraft Finance, 360 Madison Avenue, New York City, and by wire to DAP.

Note 7—Report to Bolling Field, Anacostia, D. C., thence to E. O. T. by aeroplane.

Note 8—Report to Commanding Officer, 271st Aero Squadron, Aberdeen, Md.

Note 9—Report to general, Eastern Department, for duty as department Air Service Officer.

Note 10—Report to Speedway, Indianapolis, Indiana.

Cited for Distinguished Service

The commander in chief, in the name of the President, has awarded the Distinguished Service Cross to the following named officers and soldiers for the acts of extraordinary heroism described after their names:

Sergt. (First Class) Fred C. Graveline, 20th Aero Squadron, first day bombardment group (A. S. No. 20083). For repeated acts of extraordinary heroism in action near Villers-Devant-Dum, France, and Mouzon, France, September 29 and November 5, 1918. Volunteering to act as observer and aerial gunner because of the shortage of officer observers. Sergeant Graveline started on seventeen bombing missions, successfully reaching his objective on fourteen of these expeditions, shooting down two enemy aircraft. On two occasions, while flying in the rear of his formation, he drove off superior numbers of German machines. Home address, Mrs. Josephine Graveline, wife, 537 Main Street, Springfield, Mass.

Capt. Christopher W. Ford, Air Service, 103d Aero Pursuit Squadron. For repeated acts of extraordinary heroism in action near Rheims, Farnce, March 27, 1918, and near Armentieres, France, May 21, 1918. Near Rheims on March 27th Captain Ford, while on a patrol with two other pilots, led his formation in an attack on eight enemy planes. After twenty minutes of fighting, the American formation shot down three German machines, of which one was destroyed by this officer. Near Armentieres on May 21st he again led a patrol of six planes in attacking twenty enemy aircraft. The attack resulted in ten individual combats. Captain Ford shot down one hostile plane and with his patrol routed the others. Home address, Mrs. Harriet Chuff, aunt, 462 West One hundred and thirty-first Street, New York City, N. Y.

FOREIGN NEWS

75,105 French Fliers in War

Paris, Jan. 15.—It is now permitted to give details of the progress of French aviation. When the war started there were twenty-one squadrons, 321 pilots and a total personnel of 4,342.

At the end of 1916 the personnel had increased to 75,105, the pilots numbering 6,417 and the observers 1,682. The aviation program in July, 1918, brought the number of machines to more than 6,000.

Credits voted for the French aviation service in 1914 were about $11,000,000. This sum was quadrupled in 1916, and by 1917 had exceeded $65,000,000.

Australia-London Flight Being Prepared for in Melbourne

Melbourne, Jan. 13.—A company has been formed under the name of the Aerial Service Limited of Australia to finance an aerial transport flight from Australia to London. The voyage will be made by way of the Dutch East Indies and Bagdad. The air line from Australia to London is perhaps 2,000 miles shorter than any of the routes used now.

British Ocean Flight Plan

London, Jan. 9.—The *Daily Mail* announces that several aeroplanes are under construction in different parts of Great Britain and with the assistance of the Air Ministry are planning to attempt a transatlantic flight.

The *Daily Mail* says the Air Ministry is less anxious to demonstrate that a single machine can fly across the Atlantic than that a group of machines of various types can do so. Consequently machines of more than one type are under construction in anticipation of their flying across next Spring.

Raids On England Cost 1,570 Lives

London, Jan. 11.—In raids on England by the Germans during the war, 5,511 persons were killed on injured, of whom 4,750 were civilians. The deaths numbered 1,570. An official summary of the casualties caused by German airships, aeroplanes and bombardments from the sea shows the secasualties among civilians:

Killed, 554 men, 411 women, 295 children.

Injured 1,508 men, 1,210 women, 772 children.

Three hundred and ten soldiers and sailors were killed and 551 were injured.

There were fifty-one raids by airships, causing the deaths of 498 civilians and the injury of 1,236, and the killing of 58 soldiers and sailors and the injuring of 121.

In fifty-nine aeroplane raids 619 civilians were killed and 1,650 were injured. In these raids 238 soldiers and sailors were killed and 400 wounded.

The greatest losses inflicted by Zeppelins were in raids on Norfolk, Suffolk and the home counties of London on October 13, 1915, when 54 civilians and 17 soldiers and sailors were killed, and in West Suffolk and the midland counties on January 31, 1916, when 70 civilians were killed and 112 injured. The raid on Lincolnshire, Essex and Suffolk on March 31 of the same year caused the death of 17 civilians and 31 soldiers and sailors.

The most serious aeroplane raid was that of Margate, Essex and London, on June 13, 1917, when 158 civilians and four sailors and soldiers were killed. The next in severity was that of Kent, on September 4 of the same year, when 131 soldiers and sailors lost their lives. On this occasion a crowded barracks was hit. Almost as severe as the raid on Kent was that on Folkestone, on May 25, 1917, when 77 civilians and 13 sailors and soldiers were killed. The attack on Kent, Essex and London on January 28, 1918, caused the death of 65 civilians and two soldiers and sailors.

Edward W. Beatty, President of the National Advisory Committee, Canada, who is also President of the Canadian Pacific Railway

"Aeroplane Spies" Informed Gen. Diaz

Rome, January 3.—During the period just before the great Italian offensive started considerable attention was attracted to the extraordinary accuracy of the knowledge of affairs behind the Austrian lines in possession of Gen. Diaz and his staff. It is now known that much of this exact information was secured by men who were dropped in enemy territory by Italian aeroplanes and, after an interval for observation, picked up and brought back by aviators.

During the three months just prior to the launching of the Italian drive eighty men were engaged in this perilous work. All of them had thrilling adventures and experiences. The story of Captain Romiati may be taken as representative of what might be related by any of them.

Captain Romiati served as a doctor in an Austrian hospital for ten days, and later made his escape in the guise of a cattle dealer. Lieutenants Maso and Tubero were arrested as spies, but managed to overpowe their guard and escape.

The first of the "aeroplane spies" was Giacomo Camillo de Carlo, a Venetian, who volunteered for the dangerous work. Before the war he was head designer for a widely known firm of modistes in Paris. He was a bold and resolute officer and in addition owned some property in the invaded district, where he was well known and loved by the peasants. He was carried across the Austrian lines in an aeroplane, taking with him a number of carrier pigeons. These he liberated from time to time with messages to the Italian staff. He was sheltered by the peasants, but was at last detected and forced to flee. He made his way to the seacoast and managing to get a rowboat reached an Italian port.

His success led to the formation of a regular service among bold young Italian officers. This was known as the "Giovane Italia" and played an important part in preparing for Italy's final victory.

Prince of Wales Flies in U. S. Plane

Coblenz, Jan. 11.—A flight over the Coblenz bridgehead area, a luncheon with Major-Gen. Muir and a dinner dance occupied the time to-day of the Prince of Wales who is the guest of Major-Gen. Dickman, commander of the American Army of Occupation.

The Prince professed keen pleasure in his visit to the American aerodromes and the aeroplane trip was at his request. He went up with Brig.-Gen. William Mitchell, Chief of Air Service of the Third Army. It was Gen. Mitchell's last flight at Coblenz as he is leaving for duty in the United States.

The Prince was in the air for forty-five minutes. He was taken up the Moselle, across the Rhine and then flew down the Rhine from the Lorelei rock to Neuwied, returning to the aerodrome near Coblenz. The flight was made in a two seater Spad. The Prince studied the maps during the entire flight and talked with Gen. Mitchell. He declared afterward that the flight was the most picturesque he ever had.

Albert's Plane Disabled

Paris, Jan. 11.—King Albert of Belgium, flying yesterday morning with Albert Combez, the noted Belgian aviator who finished fourth in the international aeroplane race at Rheims in 1913, was forced to land two miles from Attigny on the Aisne when the motor stalled.

Both occupants of the machine escaped injury and the plane was undamaged.

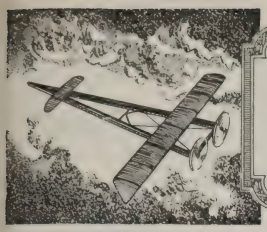
Britain Plans Air Industry Subsidies

London, Jan. 8.—The British Government may subsidize the air industry to give it the necessary financial stability for rapid peace time commercial development. The air subsidy plan is being considered by the air ministry among other proposals.

Under subsidies it is hoped private concerns will be building thousands of commercial planes and operating them as mail and passenger carrying vehicles. This, it is pointed out, would insure employment to thousands of expert aviators trained during the war. Furthermore, it would enable Great Britain at all times to have an immense air fleet at her disposal, together with the necessary trained aviators.

The success of the subsidy plan, as it has worked out in connection with the merchant marine and the motor lorries, is being cited as a strong argument in favor of air subsidies.

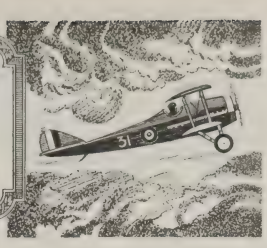
When war was declared, Great Britain had at her disposal thousands of merchant craft, many which were quickly transferred into the fighting strength of the navy immediately. Hundreds of motor lorries were sent to France from London and other cities were cited.



Germans Reluctant to Give Up Aeroplanes

London, Jan. 14.—Germany is surrendering the aeroplanes required by the armistice terms with reluctance. The total number to be delivered to the Allies in good and serviceable condition is as yet far from having been reached. German machines were simply left behind without guards in the aerodromes, and as the British advancing cavalry patrols reached them, guards were posted. In many cases the cavalry found the machines damaged or deficient in instruments or parts, and the question arises whether they were so left by the Germans or whether they had suffered owing to souvenir-hunting propensities of the civilian population.

This point is being investigated with strict impartiality. On the British sector the proportion of large bombing planes—only about twenty were left by the Germans—is very small. This emphasizes the German comprehension of the commercial possibilities of converted bombers.



The total number of German aeroplanes collected by the Royal Air Force is just over 500. It does not follow that anything like the whole of this number will be accepted as coming within the armistice definition of "in good condition." Only a small proportion are immediately flyable, and when it is established the Germans left defective machines they will not be accepted. About 170 of the total number were abandoned in open railway trucks and were, of course, left dismantled, a clear evasion of the terms. Both these and those machines which were left in the aerodromes suffered from exposure. In two cases the Germans handed over groups of machines to local municipal authorities, insisting on receipts and declarations that they were received complete, and the enormous work caused to the Royal Air Force by this haphazard manner of surrender will be realized.

Only at Nivelles were the German aeroplanes handed over in the regular manner. Nearly all these were of the newest Fokker type, though there were some Albatross scout, Pfalz, and two Junkers. These last are armored trench fighting machines with wings of corrugated aluminum, and have a pair of machine-guns which fire through the floor of the observer's cockpit.

ELEMENTARY AERONAUTICS *and* MODEL NOTES

By John F. McMahon

Model Aeroplane Building as a Step to Aeronautical Engineering

THE plate showing Tail and Rudder surfaces accompanying this article was fully described in the January 20th issue of AERAL AGE and no more need be said about these parts, but it is well to stop here and consider what these parts do and how we arrive at the figures. For instance the tail is for the horizontal control of the machine and each movement of the elevator flaps causes the machine to go either up or down, as the case may be.

Now to anybody who has studied simple Physics of Elementary Mechanics, what is to follow will be easily understood, but I would like those who have not had the above-named studies in their school life to read this article carefully and to try to understand it. This will not be at all hard because I have made everything so simple that I will be surprised to hear that anyone has failed to grasp these fundamentals.

The body of an aetroplane is like a great lever, the fulcrum or balancing point is located on paper by the use of mathematics. Of course we could easily find the balancing point if the machine were built but we must draw up our machine and balance it before building it or we would not be able to locate our wings, landing chassis, tail, etc.

To locate the center of gravity of an aeroplane proceed as follows:

Draw a side view of the machine and for accuracy make it one inch to the foot. Locate a point one inch from the outside of the propeller. This is the point about which our figures will be drawn. Now we will say our propeller weighs 19 pounds and the center of gravity of it is on a line through the center. Now we assumed that one inch equalled a foot then the propeller is one foot from our point and we write:

$$19 \times 1 = 19$$

Again we have the radiator, 50 pounds, whose center of gravity is located 1½ feet from the point and we write directly under the above:

$$50 \times 1\tfrac{1}{2} = 75$$

The motor with ignition carbureter, etc., weighs 200 pounds and the center of gravity is located (owing to the magneto being connected to the rear) a trifle behind the vertical center line of the engine, then the C. G. of this body is located about 2½ feet from this point and we write:

$$200 \times 2\tfrac{1}{2} = 500$$

The landing chassis weighs 30 pounds, and is four (4) feet from our mark so we write:

$$30 \times 4 = 120$$

The C. G. of the body is 8 feet from the point and the weight is 65 pounds, so we write:

$$65 \times 8 = 520$$

The wings complete weigh 80 pounds and the C. G. is 5 feet back, so we write:

$$85 \times 4\tfrac{1}{2} = 382\tfrac{1}{2}$$

The pilot, 185 pounds, and located 7 feet from the mark:

$$185 \times 7 = 1{,}295$$

The tail and rudder works weigh approximately 20 pounds, the C. G. being 17 feet from the point

$$20 \times 17 = 340$$

Listing these we have as follows:

Propeller	$19 \times 1 =$	19
Radiator	$50 \times 1\tfrac{1}{2} =$	75
Engine	$200 \times 2\tfrac{1}{2} =$	500
Landing chassis	$30 \times 4 =$	120
Body	$60 \times 7 =$	420
Wings	$80 \times 4\tfrac{1}{2} =$	$382\tfrac{1}{2}$
Pilot	$175 \times 6 =$	1,050
Tail and rudder	$20 \times 17 =$	340
	634	$2{,}926\tfrac{1}{2}$

dividing the sum of the last column by the sum of the first column we have

$$2{,}926\tfrac{1}{2} \div 634 = 4.6 \text{ feet approximately.}$$

Then the center of gravity of the whole machine is located 4 feet 7 inches from the point or subtracting the one foot space between the propeller and the point, the C. G. of the whole machine is 3 feet 7 inches from the propeller.

Now that we have located the center of gravity we know where our center of lifts of the wings must be, and that is in line with the C. G., or a little behind it. We can then safely call the C. G. the balancing point, axis or fulcrum of the aeroplane. The lift of the wings acts on the aeroplane, like a string fastened to an object at its center of gravity. If no outside force is acting on the object it will remain in its original state, but if you wanted to move it some force must be applied to move it in the direction wanted and this is what the rudder, tail flaps, and ailerons do.

If the aeroplane is left alone it will hold a certain course (we will forget the action of the wind to simplify matters) because there is as much weight to the rear of the C. G. as there is to the front (not in actual weight but in moments) which causes the machine to remain balanced. To change this direction or to move the object, as it were, we move the ailerons, rudder, or tail flaps which causes a pressure on these parts and moves the machine.

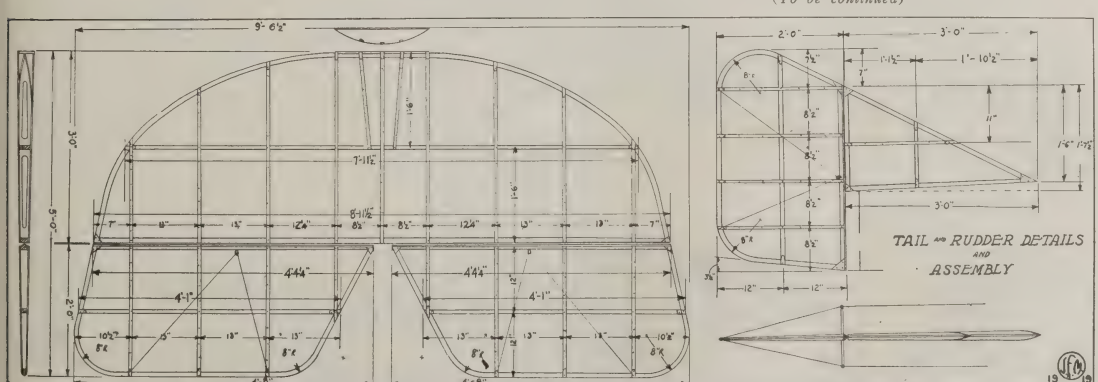
The aspect ratio of our rudder is 1.5 because it has an average of 3 feet in height and is 2 feet wide. The table which I presented in an earlier article says that the Ky or lift coefficient for flat plates aspect ratio 1.5 at 30° (which is the furtherest point that our controls will go) is .00198.

Our rudder having approximately 6 square feet of surface it will have a force at 60 m.p.h. of

$$.00198 \times 6 \times 3{,}600 = 513 \text{ pounds}$$

Now this force acts at a distance of approximately 12 feet from the C. G. and the real force is

$$42.75 \times 12 = 513 \text{ pounds.}$$



The 513 pounds is the force the rudder exerts when turning the machine.

To keep the machine from turning too sharply a damping effect is produced by placing a fixed fin just in front of the rudder which also holds the machine on a steady course.

The ailerons are figured the same way, only the moment arm is figured to the center of the ailerons instead of to the center of pressure as in the rudder. When an aeroplane is turning the outside wing gets more lift than the inside wing and causes the plane to bank heavily. This is because the outside wing is traveling faster and is covering more ground than the inside wing. By moving the aileron control so that the outer wing gets a negative action and the inner wing a positive, this banking effect is neutralized. The lateral balance of the machine is also taken care of by the ailerons.

The tail flaps are figured exactly as we figured the rudder, only we have two working instead of one. The horizontal stabilizer also acts as a damper much the same as the fin does and when the pilot pulls or pushes the control stick the machine answers surely but not too quick as would be the case if no stabilizer were used. The reader can readily see how the aeroplane body resembles a directional lever.

(To be continued)

Details of the stabilizer, elevators, fin and rudder for the Ford Motored Aeroplane

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

There was an old man of the Hague,
Whose ideas were excessively vague;
He built a balloon,
To sail to the moon,
And escape from the prevalent plague.

"Willie, we're saved," spoke the All-Highest. "I read that, according to Mr. J. A. Whitehead, it will be possible to fly to the Mid-Atlantic and alight on a floating station."

"Yes, but that's only for week-enders, All-Highest," replied the clown price, "and, anyway, I don't like the idea of water, water, all around, and not a drop to drink, as the ancient mariner hath it. Think of something better, Pa."

King of the Air

When I dance my little son on my knee,
I think of the wonders that he will see.
This bright-eyed baby just one year old,
With his sunny smile and his hair of gold.

Will my baby fly in the air one day?
Fly under the rainbow arch so gay?
Will the winds and the clouds no terrors hold,
In the age of aircraft, when all are bold?

Will he travel the world in years to be,
Swift journeying over the land and sea?
Will he laugh at time and the leagues of space,
As he drives his aeroplane on apace?

Will my baby fly in the air? Ah! yes,
And he'll see more wonders than I can guess—
My little baby, just one year old,
With his eyes of blue and his hair of gold.

I Doubt It

When a pair of red lips are upturned to your own,
With no one to gossip about it,
Do you pray for endurance to leave them alone?
Well, maybe you do—but I doubt it.

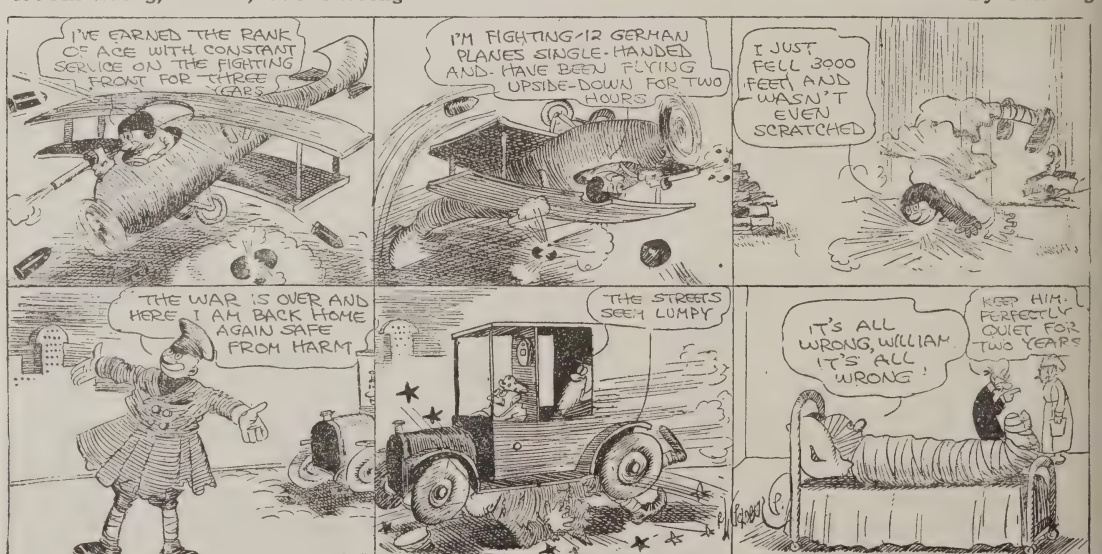
When a sly little hand you're permitted to seize,
With a velvety softness about it,
Do you think you can drop it with never a squeeze?
Well, maybe you can—but I doubt it.

When a dear little waist is in reach of your arm,
With a wonderful plumpness about it,
Do you argue the point, 'twixt the good and the harm?
Well, maybe you do—but I doubt it.

And if by these tricks you should capture a heart,
With a womanly sweetness about it,
Will you guard it, and keep it, and act the good part?
Well, maybe you will—but I doubt it.

Instructor to Cadet (after his usual wreck): "Why didn't you level off?"

Cadet: "Because the altimeter still showed one hundred feet."



Girl friend to ground officer: "What is a Keewee?"

Ground officer: "An Australian bird that does less flying than any other, but gets there just as fast."

Radio Sergeant: "Can you stay behind me two letters?"

Class: "Yes, a whole hour, at least."

financial interest in it a source of much embarrassment to him, as it was also a source of embarrassment to the officers of the Signal Corps to whom he had disclosed it. Col. Deeds discussed various plans by which he could divest himself of his interests in the company in such manner as to leave no ground for criticism. He felt that he was not justified in asking his associates to lease the ground for a nominal rental, because the largest stockholder, Mr. Schantz, represented not only his individual interest but that of the Schantz Estate, in which there was a large number of beneficiaries.

The matter was under discussion in the Department for several months and was finally referred to Mr. Montgomery of the Advisory and Consulting Committee, who, under date of June 28, 1918, wrote an opinion to the effect that if it were not for the criticisms and insinuations so extensively made with reference to the connection of Colonel Deeds with the operations at Dayton, there would be no objection to the form of lease which had been proposed, and that these criticisms suggested the advisability of unusual caution. His opinion continued with the statement that as the transaction was entirely outside the jurisdiction of Colonel Deeds and he would have no connection direct or indirect, with letting or recommending the contract, unless possibly in his capacity in connection with the Aircraft Board, Mr. Montgomery could see no legal reason why Col. Deeds' interest in the Moraine Development Co. should interfere with the transaction. Col. Deeds was not satisfied with this, however, as will appear from a letter written to Mr. Schantz by Mr. Montgomery under date of July 25, 1918, suggesting that in view of Colonel Deeds' sensitiveness to criticism, he would like to know from Mr. Schantz if a lease could not be made for a nominal consideration merely. It was shortly after this that the Hughes investigation commenced.

Returning now to the consideration of the transfer by Col. Deeds to his wife of the stock in the United Motors Co., it will be seen that what Col. Deeds really did with this stock and other stocks, is disclosed by the affidavit of George B. Smith, the financial representative of Col. Deeds, and Mr. Kettering. From this affidavit it appears that the facts, briefly recited, are these:

About August 16, 1917, Col. Deeds had stated to Mr. Smith that he had given all his interest in the United Motors Co. to his wife, and directed Smith to have it transferred to her. The certificates of stock were in Mr. Smith's custody in Dayton, and the transfer agent was the Guaranty Trust Company of New York. Not having time to give the matter his immediate attention, and because Col. Deeds was spending all his time in Washington, with the exception of week end visits every two or three weeks, the actual endorsements on the certificates were delayed until October 13, 1917, when they were endorsed by Deeds, and Smith then took them to New York and had them transferred to Mrs. Deeds on the books of the Corporation. While in New York he made demand for the pool stock referred to by Judge Hughes, which stock Smith had several times demanded in order that the stock might be transferred to Mrs. Deeds, but he was informed that the stock was not ready for delivery. Prior to going to New York on this occasion Smith notified Mrs. Deeds that he was going there to have the stock transferred to her name on the books of the corporation, and Smith stated that Mrs. Deeds appeared to know all about the transaction, and to understand that the transfer was to be made. After the transfer was made, Smith himself, who had previously been accustomed to looking after Mrs. Deeds' business affairs, kept the certificates for her, and Col. Deeds had no control over them. When the pool certificates were finally transferred to Mrs. Deed's name, Smith also kept them for her. The stock transferred to Mrs. Deeds was less than 2% of the capital stock of the United Motors Corporation.

The statement of assets made by Smith under date of August 31, submitted to Colonel Deeds, was intended to show and did show the condition of Colonel Deeds' interests as they appeared on the books of the various corporations concerned. As the stock had not been actually transferred on the books, the United Motors stock appeared on that statement to stand in the name of Colonel Deeds.

Judge McCann, the counsel for Colonel Deeds, who has been hereinbefore referred to, in an affidavit submitted herewith states that the plan of action for Colonel Deeds to pursue had been outlined by him (McCann); that McCann prepared all the documents in connection therewith, including the two letters to the Aircraft Production Board and the Secretary of War; that the language of the documents was his own; that the work was done under pressure, without opportunity for mature deliberation; that Colonel Deeds' appointment had been made; that there was apparently great need for haste in all departments of aircraft work, particularly the work of production; that Colonel Deeds' instructions were to take such steps promptly as might be necessary to carry into effect the plan decided upon; that on his return to Dayton Mr. McCann instructed Mr. Smith to make the formal transfer of the stocks as of the date of Colonel Deeds' resignation; that because of Colonel Deeds' incessant labors at Washington and his enforced absence from Dayton it took some weeks to carry this plan into effect; that the plan was fully carried out as originally intended, except as to the stock of the Domestic Building Company, which will be referred to later; that there was no reason for deceiving anyone, and no intention to deceive; that all the transactions had been in absolute good faith; that Colonel Deeds had lost heavily financially by reason thereof; and that the Government had profited greatly by the service Colonel Deeds had rendered.

The whole attitude of Col. Deeds from the time he was first approached with the request that he give the government the benefit of his services, up to the time when the investigation was commenced, taken in connection with his large financial sacrifices in relinquishing salaries aggregating $85,000 a year, as well as interests in the various companies with which he had been connected, precludes the thought that he was guilty of conduct unbecoming an officer and a gentleman in that "with intent to deceive" he officially stated to the Aircraft Production Board that he had made bona fide transfers of his stock in the United Motors Company, knowing this statement to be false. It will be observed that the "intent to deceive" is an essential element of the offense.

It is recommended that no court-martial proceedings be instituted against Col. Deeds based upon the statements in his letters to the Secretary of War and the Aircraft Production Board so far as they concerned the transfer of his stock in the United Motors Co., because: (1) Col Deeds at the date the letter was written had made an informal gift of the stock; (2) he had instructed Judge McCann to arrange promptly the necessary transfer; (3) the actual transfer was delayed because of Colonel Deeds' absence from Dayton, necessitated by his continuous and unremitting labor for the Government at Washington; (4) the formal transfer was subsequently made; (5) there was a total absence of intent to deceive

New Book on Practical Aeroplane Rigging

For Aviation Officers and Mechanics

Approved for use in U. S. Navy Aviation Mechanics Schools

Written by

JAMES T. KING, formerly mechanic with Canadian and American Curtiss Aeroplane Factory and Royal Flying Corps; now instructor Aviation Dept., Dunwoody Institute; and

NORVAL W. LESLIE, Flight Sub-Lieutenant, R.N., instructor Aviation Department, Dunwoody Institute.

This book is well illustrated and takes up types, parts, alignment, care and maintenance of machines in a practical way; also the theory of flight. Only new book of its kind on Rigging.

Price $1.50

THE DUNWOODY INSTITUTE
818 Superior Avenue, Minneapolis, Minnesota.

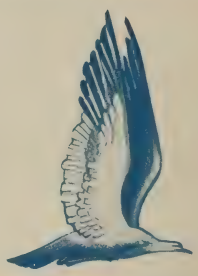
Vol. 8, No. 21 FEBRUARY 3, 1919 10 CENTS A COPY

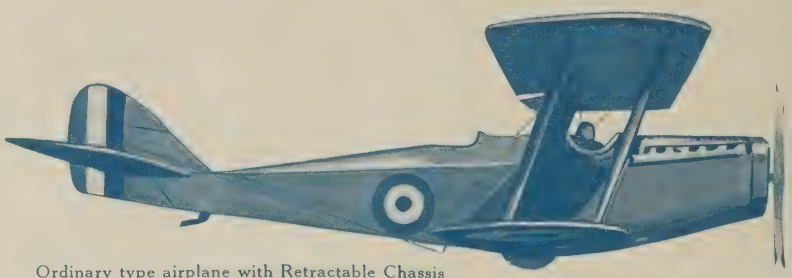
Admiral Fiske's idea being put into effect. The Sopwith torpedoplane dropping a torpedo over the North Sea

American Express Company Ready to Handle Aerial Express



The Curtiss Model K-6 and K-12 Aviation Motors Described

BLISHED WEEKLY BY THE AERIAL AGE COMPANY, INC., FOSTER BUILDING, MADISON AVENUE AND FORTIETH STREET, NEW YORK CITY
scription: Domestic, $4. Foreign, $6. Entered as second-class matter March 25, 1915, at the Post Office at New York, under the act of March 3rd, 1879



EVERY FIRST CLASS AEROPLANE REQUIRES A RETRACTABLE CHASSIS

Can you Imagine These Birds in a Race for Speed?

Or These Planes in a Speed Test?

Ordinary type airplane with Retractable Chassis

Ordinary type airplane without Retractable Chassis

The following is an extract from a report by Mr. L. V. Kerber on one of the latest U. S. Army airplane designs:

Effects of retracting the Chassis

Total Resistance of Extended Chassis 59.6*
Total Resistance of Retracted Chassis 11.0

Difference 48.6

At 100 miles per hour the structural resistance with chassis extended is 230* plus 48.6 ..... 278.6

By retracting the chassis the structural resistance is decreased $\frac{48.6*}{278.6}$ 17.4%

At 100 miles per hour the total resistance with chassis extended is 210 plus 278.6 ..... 488.6*

By retracting the chassis the total resistance is decreased $\frac{48.6*}{488.6}$ 10%

By retracting the chassis the maximum horizontal velocity is increased $\frac{145}{137} - 1$ 6%

In order to meet both aerodynamical and practical demands the following patented features will be recognized as indispensable to any type of retractable chassis:

1—The chassis should be equally strong in spite of its retractable feature.
2—It should not weigh more including retracting mechanism than the ordinary chassis.
3—It should neither occupy useful space when retracted nor require an enlarged fuselage to house it.
4—It should be adapted in strength as an alighting device in any intermediate position between fully extended and fully retracted, both in case the pilot should make a hurried descent and in order to make available a ready means of varying the position of the chassis relative to the centre of gravity of the aeroplane.
5—It should automatically close the housing recesses so that the fuselage or wing skin forms a flush surface when chassis is retracted.
6—The gage and tread of the chassis should be independent of the width of the fuselage.
7—It should utilize the forces of flight, since they are always available, for power to retract and extend and such action should be entirely automatic when released by the pilot.

For Engineering data and License apply to

Capt. Jas. V. Martin, Martin Aeroplane Factory, Elyria, Ohio.

AMERICAN EXPRESS COMPANY READY TO HANDLE AERIAL EXPRESS

MR. ALAN R. HAWLEY, the president of the Aero Club of America made public on January 28 a report of the Aerial Transportation Committee of the Club, announcing that the American Express Company is ready to handle aerial express and will do so as soon as aerial transportation lines are established throughout the country.

The American Express Company, the report states, believes that the great speed of the aeroplane makes it a valuable means of transportation, and that many people will be glad to pay extra to have their packages delivered in half or one third of the time required by other means of transportation.

It has been estimated that aerial express could be carried profitably at a charge of two dollars per pound for packages of a given size between New York and Chicago.

A twin motored aeroplane can make the New York-Chicago trip in about seven hours, without stopping, carrying over one thousands pounds of express matter.

Such an aeroplane, made to order, will cost about $20,000. In future, when they are built in large number, they will probably cost only $10,000.

The life of the motors, if run throttled down, is over 500 hours of flying. The life of the plane itself is greater.

A low compression Liberty motor burns about twenty gallons of gasolene an hour. Two Liberty motors on a plane would, therefore, consume about 280 gallons of gasolene for the New York-Chicago trip. The 300 h. p. Hispano-Suiza and the new 400 h. p. Curtiss motor, consume less gasolene than the Liberty.

It appears that it will be possible to get between four and seven miles to the gallon of gasolene in operating air lines.

Mr. Ralph E. Towle, the manager of the Travel Department of the American Express Company, has gone to Europe to investigate the plans and methods of aerial transportation in Europe. Mr. Albert R. Green, the assistant manager, is receiving the hearty co-operation of the Aerial Transportation Committee of the Club. Mr. Glenn H. Curtiss, the famous aeroplane manufacturer, who is a member of the Committee, took Mr. Green through the Curtiss aeroplane factory at Garden City to give him an opportunity to see the large aeroplanes under construction, and to see a 50-passenger air yacht.

"The action of the American Express Company is an epoch-making event in aeronautics," said Mr. Hawley.

"It will be a great inducement to the pioneer concerns that are planning to establish aerial transportation lines throughout the country to know that the American Express Company is ready to co-operate with them—and probably use the major part of the carrying capacity of their planes, no matter how large they may be."

The members of the Aerial Transportation Committee of the Aero Club of America are as follows: Rear-Admiral Robert E. Peary, Chairman; Col. Bion J. Arnold, Roger W. Babson, Sir F. W. Baillie, Major T. F. Baldwin, U. S. A., Bernard M. Baruch, Capt. R. A. Bartlett, Alexander Graham Bell, Major August Belmont, U. S. A., Laurence V. Benet, Walter Berry, Lieut. Commander P. N. L. Bellinger, U. S. N., Lieut. Commander W. Starling Burgess, U. S. N., James M. Beck, General Theodore A. Bingham, Lieut. Col. James A. Blair, Jr., William H. Bliss, Col. G. C. Brant, U. S. A., Rear Admiral Mark S. Bristol, Lieut. Col. A. R. Christie, Col. C. C. Culver, U. S. A., Lieut. Godfrey L. Cabot, U. S. N., Manuel Estrada Cabrera, President of Guatamala, Gianni M. E. W. Miller, Harry Bowers Mingle, Wm. H. Page, Augustus Post, George W. Perkins, L. C. Phipps, Col. James Prentice, Major Cushman A. Rice, U. S. A., Prof. C. L. Poor, R. B. Price, N. G. Rost, Hon. William G. Sharp, Allan A. Ryan, Alberto Santos-Dumont, Herbert L. Satterlee, F. A. Seiberling, J. DeMont Thompson, Rodman Wanamaker, Lt. Col. Wm. Thaw, Brig. Gen. Cornelius Vanderbilt, W. K. Vanderbilt, G. Douglas Wardrop, Felix M. Warburg, Sidney B. Veit, Henry Woodhouse, Major Orville Wright, Harry Payne Whitney, John N. Willys, Evan J. David, K. M. Turner.

NEW YORK POLICE TO HAVE VOLUNTEER AERO SQUADRON

FOLLOWING a conference with Police Commissioner Enright, Special Deputy Police Commissioner Rodman Wanamaker, Inspector Dwyer, Special Deputy Police Commissioner Allan A. Ryan, Special Deputy Commissioner Wallis, Dr. John A. Hariss, Special Traffic Commissioner, and other high officials of the Police Department and the Aero Club of America officials, the chief of the Aviation Section of the New York Police Department, Colonel Jefferson De Mont Thompson, made public the plans to organize an aero squadron to be part of the New York Police Department.

Colonel Thompson also discussed the plans with Colonel William A. Bishop, the Canadian Ace, who has 72 enemy aeroplanes officially credited to him, at the Aero Club of America's reception to Colonel Bishop, and Colonel Bishop approved of the plan heartily.

Captain Arthur J. Coyle, commanding officer of the First Aero Squadron of the American Expeditionary Forces, who also was at the Aero Club of America, was enthusiastic over the plan and assured Colonel Thompson of his co-operation in organizing the Police Aero Squadron.

It has been decided that the Aviation Section of the New York Police shall be a volunteer body.

The formation will be the aero squadron formation as prescribed by the United States Government, which provides for 20 officers, including the executive, technical, medical, etc., and 12 pilots. As a rule there are 154 non-commissioned officers and enlisted men to an aero squadron. The number of officers and men per aero squadron have been changed from time to time, and in organizing the Police Aero Squadron, the Police authorities will comply with the latest United States Army formation requirements.

This will make the New York Police Aero Squadron of military value and will set the standard for police aviation sections, which other cities, no doubt, will organize in the near future.

An aero squadron consists of three aero companies. The aero company is the smallest aero tactical unit, and the Aero Club of America has suggested that smaller cities begin by organizing an aero company. Larger cities will be urged to organize aero companies.

Leading New York aces will be invited to join the Aero Squadron of the New York Police. Colonel Thompson stated today that he was asking the following American Aces, who are residents of New York, to join the New York Police Aero Squadron:

Captain Edward V. Rickenbacker, the foremost automobile driver, who is the premier ace of the American Air Forces, having 26 enemy planes to his credit.

Lieut. Col. William Thaw, the dean of American Aviators, who has 5 enemy planes to his credit.

Major James A. Meissner, who has 8 enemy planes to his credit.

Major Cushman A. Rice, who commanded 4 American Aero Squadrons which co-operated with the British forces and who was wounded and gassed at the second Somme battle.

1st Lieut. Lansing C. Holden, who has 7 enemy planes to his credit.

2nd Lieut. Howard Brodick, of Brooklyn, who has 6 enemy planes to his credit.

Lieut. F. M. Symonds, who has 5 enemy planes to his credit.

Three other aces—Lieut. E. P. Curtis, of Rochester, New York, who has 6 enemy planes to his credit; Lieut. E. M. Haight, of Astoria, New York, who has 5 enemy planes to his credit; and Lieut. H. H. George, of Niagara Falls, New York, who has 5 enemy planes to his credit, will be asked to join the New York Police Aero Squadron, if their respective cities do not need their services.

Colonel Thompson attended the reception given by the Aero Club of America to Colonel Bishop, the Canadian Ace, who has been credited officially with 72 enemy planes, and discussed the plan of the New York Police Aero Squadron with Colonel Bishop and the Aero Club of America officials.

Colonel Bishop was greatly interested in the project, which he approves heartily.

Colonel Bishop stated that the example of New York City will, no doubt, be followed by every progressive city in the world in the very near future.

AWAITING THE AERIAL LIMITED

AMERICA is falling behind England in aerial passenger transportation. Already two British companies are regularly operating air lines between London and Paris, carrying people for £15 a passenger each way and on schedule time, making the round trip between breakfast and dinner and allowing four hours in either city for transacting business. An aerial express is also flying a London-Manchester-Liverpool route. Another British company has sent out a bi-motored biplane with six civilians from London to Delhi, India, via Brindisi, Marseilles, Otranto, Cairo, Damascus, Bagdad, Bushire, Bandar Abbas and Karachi—a total distance of nearly 4,000 miles. Major General Salmon, in a bi-motored military machine of the same type, has already flown 3,950 miles from Cairo to Calcutta. This same biplane had previously negotiated the flight all the way from London to Cairo and had done extensive bombing of the Turks in Palestine.

In the United States only two aerial transportation companies have displayed any life. There are no machines in regular passenger service on schedule from city to city.

With regular aerodromes—even one hundred miles apart—passengers can be carried in standardized, bi-motored aeroplanes safely and on schedule time. If one motor stalls the other has sufficient power to fly the aircraft to its destination, with no greater loss of time than characterizes regular, long-distance train service in this country. Comfort against the cold is provided by electrically heated clothing, and, of course, no kind of earth travel compares with flying for breadth of view and exhilaration.

The greatest present need for popularizing American aeronautics is for the manufacturers of aircraft to put into operation at once a passenger-carrying air line and to transport passengers through the heavens from one city to another safely and on schedule time. This can easily be done by three or four types of bi-motored aeroplanes now completed in this country. 'Buses aerially navigating the distance between New York and Washington, via Philadelphia and Baltimore, could be put into operation any day, starting from Belmont Park and landing at the same aerodromes as the aero mail ships now use. Indeed, the aero mail between this city and the capital has already made an enviable record of 350 consecutive flights through all kinds of weather—from thunder to snow storms—with only three delays.

The Manufacturers' Aircraft Association is, perhaps, the most logical organization to start such an enterprise at once. Several of its members have constructed bi-motored aeroplanes which could carry a score of passengers between those four cities without danger and in great comfort. So many people are anxious to visit cloudland in a heavier,than-air machine that the line would soon pay for itself. By doing this they would greatly advance the glory of American aeronautics.—Editorial in the N. Y. *Tribune*.

THE NEWS OF THE WEEK

Senator Chamberlain Calls for Department of the Air

Washington, January 22nd.—Senator Chamberlain sounded a call for aerial preparedness for the next war before the Senate Military Committee. As a necessary foundation for a strong aeronautic policy Senator Chamberlain urged the establishment of a Department of the Air, with its head a Cabinet Member. The Senator said:

"The United States should profit by the experiences of the war with Germany and formulate a constructive programme accordingly. We ought to continue to manufacture aeroplanes in reasonable quantities, but more than all we should endeavor to develop mechanical flight so as to be able, should the emergency arise, to achieve and maintain control of the air.

"I do not think that this country should endeavor to keep up an air programme to the extent aimed at while we were at war, but developments in aeronautics more than in all other sciences bearing on intimate relationship to national defence is absolutely essential. Otherwise America cannot hope to attain that position of supremacy in aerial navigation which she should have attained during the war had our executive efforts been properly co-ordinated.

"The air problem in the future seems to rest on efficient co-ordination. It is for this reason that we—speaking for a majority of the members of the Senate Military Affairs Committee—recommend a unification of effort, and still urge such a policy. What I would like to see would be the creation of a separate air bureau or department, whose head shall sit in the Cabinet along with the Secretaries of War and Navy."

War Department Permits Publicity On War Contracts

Washington, January 19th.—According to an official statement issued by the Director of Purchase, Storage and Traffic, War Department, the revocation of the clause or clauses in War Department contracts, prohibiting the publication of information in respect to such contracts, having been approved by the Secretary of War, the provisions of such prohibitory clauses are revoked. Contractors are, therefore, authorized and permitted to furnish the public information concerning War Department contracts and orders received by them.

"Aeronautical Day" At Brooklyn Rotary Club

Brooklyn, N. Y., January 22nd.—Among the notables of Aeronautics who attended the luncheon meeting of the Brooklyn Rotary Club at Hotel Bossert was Mr. Alan R. Hawley, President of the Aero Club of America; Mr.. Augustus Post, Secretary of the Aerial League of America; Mr. Charles Jerome Edwards, Vice-President of the Aero Club of America and President of the Rotary Club; Captain Robert A. Bartlett, Captain of the S. S. *Theodore Roosevelt* when Admiral Peary discovered the North Pole, and who is planning a flight to the North Pole next summer.

Speaking of the projected aero flight to the Pole, Capt. Bartlett said: "People ask what is the use of making these explorations, but if the British Government had sat down and not explored the world the British flag would not today be flying from every quarter of the globe, and if we do not explore these white spots on the map and draw some lines in them some other nation will."

Department of Military Aeronautics Disposing of Surplus Material By Auction and Sealed Bids

New York, January 23rd.—The Aero Club of America has recently received a communication from the Department of Military Aeronautics requesting that attention be called to public auctions and sale under sealed bids of practically every item used on a flying field.

Communications requesting information on this subject should be addressed to Lieutenant H. G. Quirt, Supply Station, Salvage Branch, Department of Military Aeronautics, Washington, D. C.

Officers Can Collect Back Flying Pay

Washington, D. C., January 23rd.—According to reliable information, officers commissioned since July 1st, 1918, can collect 50% increase in pay for all the time they have been on flying duty as enlisted men since July 1, 1918. The procedure to be followed in obtaining back flying pay is to write to the Commanding Officer of the field at which training was received and request an order placing them on flying status on July 1st and taking them off on the date of this commission. This order, together with a statement of claim due, should be sent to the Auditor, War Department, Washington, D. C.

Flies 9 Hours 21 Minutes

Miami, Fla.—What is said to be a new aerial endurance record was established on January 23 by Ensign F. Dalrymple, of the local air naval station, who remained in the air continuously for nine hours and twenty-one minutes.

Driving a HF-2 machine and accompanied by a mechanic, Dalrymple left the air station here at 8:10 a.m. and remained in the air until 5:31 p.m., he made two trips to Key West and back before landing. The previous endurance record, it is said is for nine hours and one minute.

The machine used on the flight was specially constructed and equipped with a Liberty motor.

Col. Bishop Predicts Many Commercial Uses for Aeroplanes

New York, Jan. 25.—At a luncheon given in honor of returning war aviators by the Aero Club of America, Col. William A. Bishop, Canadian "ace," with seventy-two German planes to his credit, predicted confidently that both giant and one-engine planes will be making trans-atlantic flights within six months.

"Eight British firms are building planes to fly across the ocean," said Col. Bishop. "The Vickers Company will soon put out a machine of unprecedented size for that flight, but, for my part, I think the trip can be made in a single-engine plane. Such small machines are making regular trips between Montreal and Toronto.

"Three firms will have aerial garages in Canada within a year. Then one may call up a garage, a plane will call for him and he will be off on the fastest and most delightful journey he ever made. These machines will carry freight too.

"To encourage the building of planes for commercial purposes, laws governing aerial traffic must be made and obeyed," Col. Bishop went on. "There must be rules of the air, just as there are rules of the road. And the customs officers will have to be on the sharp lookout for aerial smugglers.

"In British Columbia aeroplanes are being used most successfully to detect forest fires and prevent their spread. The aviator either flies and gives the alarm in person or drops especially prepared chemical bombs. All Canada will adopt this system to protect her valuable forests, I think."

John Burroughs, the perennial naturalist, asked the Colonel if he would take him on a transatlantic air voyage. Col. Bishop smilingly promised that he would.

Aero Exposition Plans Maturing

New York, Jan. 27.—Owing to the large number of exhibits offered, the Manufacturers Aircraft Association has found it necessary to lease for its Annual Aeronautical Exposition not only Madison Square Garden but the 69th Regiment Armory as well. It was at first planned to hold the exposition late in February, but developments in co-operation with the Government made advisable a slight change in dates. As a result the

The Aero Club of America reception to Lieut. Col. William A. Bishop, R. A. F. and Captain Arthur J. Coyle, Commander First Aero Squadron, American Air Force. From left to right: Henry Woodhouse, Captain Arthur J. Coyle, U. S. A.; Colonel Bishop, R. A. F. (in civilian clothes); Rear Admiral Bradley A. Fiske, U. S. N.; Captain Roger B. Whitman, U. S. A.; Lieut. Horace B. Wells, Augustus Post, members of the U. S. Army and Navy Air Service; William Hawley, Lieut. Eytinge, Canadian Air Service; Lieut. W. D. Adams, and Lieut. Edwin C. Moore. About 200 people were present, including Robert A. Bartlett, famous explorer; John Burroughs, the famous naturalist; Dr. Terry, Mr. A. J. Marcuss, Mr. M. M. Marcuss, Major H. A. Bubb, Lieut. H. S. Koch, Lieut. James Crommery, Colonel J. DeMont Thompson, Robert Graves, Henry A. Wise Wood, Mr. J. C. Cullinan, Lieut. M. Gilbert Whitman, Lieut. DeWilder Atkinson, R. A. F.; Lieut. Nelson, A. S. A.; Lieut. N. W. Siberman, Lieut. K. M. Murray, G. Douglas Wardrop, managing editor of Aerial Age; Dr. C. A. Lawrence, Mr. E. A. Townley, Lieut. Beckwith Havens, U. S. N.; Evan J. David, business manager of Flying; Leroy B. Gulotta, editor of Air Power; Major Cushman A. Rice, etc.

exposition will be held from March 1 to March 15.

Arrangements for the exposition have brought the Show Committee of the Association into communication with an extensive range of industries. The exhibitors, it is predicted, will include not only the aeroplane and motor manufacturers but the makers of parts, accessories and subsidiary elements that enter into the construction of this most modern product of science and industry—the flying machine.

The members of the Manufacturers Aircraft Association are completing their show plans as rapidly as possible and the principal companies have already made definite plans for space, exhibits and the manner of display. It is planned to have all aeroplanes where they may be seen close at hand. In the case of the Army and Navy it is understood that soldiers and sailors trained in flying, gunnery or mechanics will be stationed at the various exhibits to explain to the people what each part means and how it functions.

It is not the aim to segregate the commercial, naval and military exhibits, but to distribute them throughout both the Garden and the armory. Visitors will have an opportunity to see not only the products of American aircraft industry but will be able to see examples of commercial and military construction from Great Britain, France and Italy. War trophies, of course, will represent Germany.

The Performance of the Christmas Bullet

In the description given of the Christmas Bullet in AERIAL AGE on January 20, the ceiling of the machine was given as 14,700 feet. This reference was to the climbing efficiency of the machine, and not the actual ceiling. The actual ceiling has been computed to be close to 34,700 feet.

The climbing efficiency is 1,700 feet per minute; that is to say, the machine is capable of climbing 1,700 feet per minute until an altitude of 14,700 feet is reached, from which point, the climbing rate naturally decreases until the actual ceiling has been reached.

National Special Aid Society to Aid Bartlett Air Polar Trip

Women are to have their part in the Roosevelt Memorial Arctic Expedition which is to start by aeroplane for the polar regions in June of this year. The Aviation Committee of the National Special Aid Society, Mrs. William Allen Bartlett, chairman, has just voted to contribute the complete hospital equipment and supplies for the expedition. This expedition will be financed by the Aerial League of America and be in charge of Captain Robert A. Bartlett, who was Captain of the S. S. *Roosevelt* in both of the Peary expeditions, and Commander of the McMillan Relief Expedition, etc.

The funds for this donation will come from the Treasurer and Trinket Fund of the society, which, working for the aviators of the United States Army, has raised nearly $100,000 to supply them with warm garments and other necessities and to aid their dependents in case of disaster. The women voted unanimously to make this gift to the expedition; it will be arranged with expert medical and surgical advice, and they may increase the gift when the cost of the equipment is learned.

Dirigible Made 1,200 Miles in 29½ Hours

The big navy dirigible, C-1, which recently sailed from Rockaway to Key West, covered the

D. G. Caywood, special field representative of the Black & Decker Co., of Baltimore, manufacturers of precision apparatus

1,200 miles in twenty-nine and on-half hours actual time in the air, according to its commander, Capt. Stanley V. Parker, who reported to Washington yesterday. He came back on a train, which required sixty hours.

Two other remarkable endurance flights by the Navy Dirigible A-236 from the naval air station at Key West, one lasting 32 hours and covering 750 miles, and the other 40 hours and 48 minutes, and covering about 850 miles, constituting a service record, were described in official reports made public recently.

Rising winds and threatening storm stopped the first flight November 24, although sufficient fuel and oil remained for 8 more hours. During the first 10 hours the ship was lightened 300 lb. by consumption of gasoline. Her crew brought her down to within 50 ft. of the sea and with buckets and line took up enough water to restore her propeller balance.

The second trip, made December 24-25, was made under overcast skies with a wind ranging from 20 to 36 miles an hour. The propelling motor was stopped only twice, for 3 minutes each time, to fill the oil reservoir.

Army Reorganization Bill Provides for Reduced Air Service

Washington.—Indications of the size of the future Air Service of the Army is given in a proposed bill drawn up by the War Department this week. The bill, which will probably be held in abeyance pending possible developments in Europe, calls for an Air Service of 1,923 officers and 21,853 enlisted men. The officers include one major general, one brigadier general, twenty-two colonels, forty-five lieutenant-colonels, 126 majors, 438 captains, 696 first lieutenants and 594 second lieutenants. An organization of this size would require approximately 2,000 aeroplanes in constant service.

New Air Service Insignia

Washington.—An insignia for fliers has been approved with certain changes as follows: (a) Military aviators, junior military aviators and reserve military aviators: a device of oxidized silver consisting of a pair of wings with the shield between; to measure 3 in. from tip to tip.

(b) Military aeronaut, junior military aeronaut and reserve military aeronaut: a device of oxidized silver consisting of a pair of wings with a balloon between; to measure 3⅛ in. from tip to tip.

(c) Observer: an oxidized silver single wing to the left of the letter "O" in bright silver; the "O" to encircle the letters "US" in oxidized silver in relief on an oxidized silver background; the device to measure 1⅞ in. in length.

Flying instructors: gilt insignia of the same design and size as the insignia for officers of the Air Service, omitting the propeller; to be worn just above the right cuff on all coats.

Conditions for Tests of Experimental Aeroplanes Announced

The following regulations were authorized by General Kenly, January 14, 1919:

1. The Chief of the Technical Section is charged with the responsibility for all tests of experimental aeroplanes at Air Service Fields.

2. Requests by private enterprise for permission to conduct *Unofficial Tests* of experimental aeroplanes at Air Service Fields may be granted under the following conditions:

(a) Such tests will be conducted at McCook Field, Dayton, Ohio, unless otherwise permitted by the Director of Military Aeronautics.

(b) Such tests will be entirely at the owner's risk and expense and he shall supply the pilot therefor. No Air Service pilot will be permitted to engage in these tests.

(c) Flight tests will be permitted only after a technical examination by a representative of the Technical Section. If, in the opinion of this officer, the aeroplane is unsafe to fly, no flight will be permitted at an Air Service Field.

3. *Official Tests* of experimental planes will be authorized only at McCook Field, Dayton, Ohio, and under the following conditions:

(a) The owners of such aeroplanes must submit two models—one for destruction test and one for performance test.

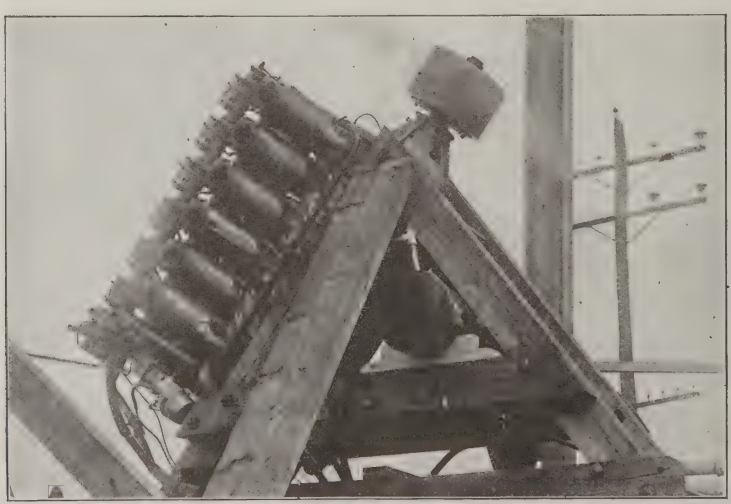
(b) Tests will be at Government expense and the flight test will be made by an Army pilot detailed by the Chief of the Technical Section.

(c) Flight tests will be permitted only after a technical examination and sand-test by a representative of the Technical Section. If, in the opinion of this officer, the aeroplane is unsafe to fly, no flight will be permitted at an Air Service Field.

4. Pilots inexperienced in flying experimental aeroplanes will not be permitted to fly such planes until after they have been placed "in production."

5. Commanding Officers at Flying Fields will be held strictly responsible that no flights are made at their fields in violation of the foregoing instructions.

1,000,000 Ship Tons Saved by Efficient Aeroplane Packing



The studies carried on by Bureau of Industrial Research recount a saving of space in aeroplane shipment as follows.

The studies which were made in reduction of space necessary in which to ship aeroplanes resulted in the cutting of the size of the boxes needed for a single machine 50 per cent. This would mean that with limited transportation facilities double this number of planes could be shipped in a single trip across the ocean. In one instance alone 50 carloads of freight were so repacked as to require the space of only 15 with its proportionate saving in cargo space.

To the work of the Bureau of Industrial Research of the Purchase, Storage and Traffic Division is due the conservation of space in thousands of freight cars and at least a million ship tons. Credit is also due the bureau for reduction in losses due to faulty and defective packing. As a result of the efforts of its experts, millions of dollars were saved in packing materials and many more millions of invaluable tonnage and cargo space for the use of the Army.

Pioneer Military Air Heroes' Photos Sought

The Director of Military Aeronautics desires to have photographs of the officers named below, who were killed in aeroplane accidents, and for whom fields of the Air Service have been named. So far it has been impossible to get in touch with any relatives or friends of these men, all of whom died several years ago and whose records in the War Department are incomplete: Lieut. Moss L. Love (Cavalry), Lieut. Joseph D. Park (Cavalry), Lieut. Lewis C. Rockwell (Infantry), Lieut. Lewis W. Hazelhurst, Jr. (Signal Corps), and Lieut. Eric L. Ellington (Cavalry).

A Liberty Twelve "climbing" on the test block at the Trego Motors Corporation

The AIRCRAFT TRADE REVIEW

Packard Motor Co. to Market Two Passenger Biplane

Detroit.—The Packard Motor Car Co. is shortly to place on the market a two-seated biplane which is to be sold through Packard dealers at a figure close to $15,000. The Packard Company, therefore, becomes the first manufacturers of passenger cars and trucks to take up, in a commercial way, the production of aeroplanes for general use.

The decision of the company to enter this new field is not altogethr surprising in view of its experience in the development of an aeroplane engine of its own and of the intimate relationship betwen the Packard engineering force and the finished Liberty engine. It was largely through the efforts of Jesse G. Vincent, at that time vice-president of engineering of the Packard Company, that the Liberty engine was designed and brought to perfection.

Beyond the fact that the machine is to be a two-seated biplane, little regarding the design and construction has been permitted to become public. It is expected, according to "Automotive Industries," that the first machine will be ready in from thirty to sixty days, and it is planned to supply them to dealers as rapidly as possible. Already the Chicago dealer has ordered one and other dealer organizations see in the machine a potential market composed of well-to-do sportsmen.

That dealers will take readily to the sale of planes, and that they believe in the possibilities of selling such machines is indicated by the fact that in both Milwaukee and Philadelphia, dealers have recently arranged to handle aircraft. George W. Browne, Milwaukee distributer of Overlands, is to take on the distribution of Curtiss machines, which are made by the Overland interests; and in Philadelphia, Isenberg Brothers have prepared plans and shortly will erect a building to be used for the exhibition and sale of heavier-than-air machines. The company will sell both new and used machines.

U. S. Naval Aircraft Production

Washington, Jan. 20.—The U. S. Naval Aircraft factory at Philadelphia produced aircraft valued at $5,435,000 up to the time the armistice was signed, according to an announcement made recently. It had completed, ready for shipment, 183 twin-engine flying boats at an average cost of $25,000. It had also produced 4 experimental Liberty engine seaplanes carrying the Davis non-recoil gun, at a cost of $40,000 each, and 50 sets of twin-engine flying boat spare parts worth $10,000 per set. In addition, considerable minor experimental work and overhauling of machines from other stations was done.

Bosch Magneto Company Officially Becomes American Bosch Magneto Corporation

On December 7th, 1918, the Alien Property Custodian of the United States sold the entire property holdings, assets and patent rights of the Bosch Magneto Company to the highest bidder. The organization papers, drawn up for inspection as to the Simon Pure Americanism of the purchasers, reveal some interesting facts in connection with the successors, the American Bosch Magneto Corporation.

The Officers of the new company are: A. T. Murray, President; George A. MacDonald, Vice-President and Treasurer; A. H. D. Altree, Vice-President; Leon W. Rosenthal, Vice-President; J. A. MacMartin, Secretary and Assistant Treasurer. The Directors are: A. T. Murray, H. C. Dodge, Martin E. Kern, Duncan C. Holmes, George A. MacDonald, Philip L. Spalding, Henry N. Sweet, H. B. Benedict, C. H. Dwinnell.

Mr. Murray, President and Director of the new company, is also President of the Bethlehem Motors Corporation, of Allentown, Pa. Besides managing the Magneto Corporation, Mr. Murray will continue as the active head of the Motors Corporation.

Mr. MacDonald, Vice-President and Treasurer of the new company, is also President of the Chicopee National Bank, Springfield, Mass.

Mr. Kern is President of the Penn Counties Trust Company, Allentown, Pa., and is also Treasurer of the Bethlehem Motors Corporation.

Messrs. Sweet and Benedict are connected with Hornblower & Weeks, Bankers, of Boston and New York.

Mr. Dwinnell is Vice-President of the First National Bank of Boston, and Mr. Holmes is Vice-President of the Chase Securities Corporation, New York. Mr. Dodge is Chairman of the Board of Directors of the Gray & Davis Company, of Boston, and President of the H. A. Wood Company, also of Boston. Mr. Spalding is President of the New England Telephone and Telegraph Company, Boston, Mass.

The American Bosch Magneto Corporation has taken over the entire holdings and organization of the old company, including the great Bosch Works at Springfield, Mass., which comprises 250,000 sq. ft. in buildings alone and employs 1,500 operatives; also the complete service and selling system throughout the United States, and the entire ownership of all the United States and foreign patents and trade marks under which the old company operated. Ever since the Alien Property Custodian seized the company in May of 1918, the large plant was operated to supply, up to practically 100% of its capacity, the needs of various Departments of the United States Government in the prosecution of the war. That large output will now be devoted without interruption to the requirements of the American manufacturers and public. In addition, the American Bosch Magneto Corporation plans to greatly extend its scope of manufacture in the field of automotive industry.

From an early date, the Bosch Magneto Company manufactured electrical products of unusually high quality for the automobile and allied fields, including ignition devices such as Magnetos and Battery Systems, Lighting Generators, etc. In fact, the first Bosch Magneto dates back to 1886, although this form of ignition was not adopted by American manufacturers of automobiles until 1905. In the following year, Robert Bosch opened a New York office, and in 1908 a four-story building was acquired to meet the demands of the products then made. It is said that about 350 workmen produced eight to ten thousand magnetos a month at that time. The next important step in the growth of the Bosch Magneto Company, the title under which the German concern operated in the United States, was taken in 1911, when ground was broken in Springfield, Mass., for what is now recognized as the most modern and well-ordered factory in the motor industry.

In January, 1912, the extensive Springfield Works were completed, only to be found too small by 1914, when more than one-quarter of a million magnetos were turned out. Accordingly, the Rushmore Dynamo Works was purchased to increase the production of Starting and Lighting apparatus. Expansion still continued. Early in the fall of 1915, ground was again broken at Springfield for an addition of over 60,000 sq. ft. to the main works. The American Corporation now has in its possession all of these excellent buildings and their equipment, together with a recreation park and club house for the employees, across the street from the main factory. It is also the exclusive owner of more than 150 United States patents and a large number of United States patent applications, together with numerous foreign patents and applications. Also the well known Spark-Devil and other Bosch trade marks registered throughout the world belongs to it.

It is understood that the new organization intends to engage actively in establishing itself in a position of even greater prominence in the production of electrical apparatus for American automotive fields than the old company enjoyed before the war.

Ban On Civilian Flying Lifted

Washington, D. C., January 23rd.—According to an official announcement from the War Department, the Joint Army and Navy Board has removed restrictions on civilian flying and will issue permits upon application to all qualified civilians who have been denied the right to fly under the President's Proclamation of February 28, 1918.

Applications for permits should be addressed to the Joint Army and Navy Board on Aeronautic Cognizance, Building "D", 6th and B Streets, N. W., Washington, D. C. Attention of Lieut. L. G. Haugen.

In making an application for a flying license the civilian is requested to forward a copy of his or her certificate or license showing that the individual is qualified as a pilot.

The application must be supplemented with full information as to the nature of the aerial project contemplated; the financial backing; the means to be taken to insure the reliability of motors and the upkeep of planes; types and condition of planes, and the number of hours each has been flown. The number of mechanics to be employed should also be stated.

In short a complete detailed report is desired, and standard forms of application are furnished upon request to the Secretary, Lieut. L. G. Haugen, Division of Military Aeronautics.

It is anticipated that the lifting of this ban will result in the re-opening of various flying schools and increased activity on the part of manufacturers.

London-Buenos Aires Airship Trip Planned

London—Sir Woodman Burbridge announces that he has booked passage from London to Buenos Aires aboard the airship which it is proposed shall undertake the trip next August. He says the preparations are being made by the Vickers interests, and it is expected that the voyage will not take more than six days.

Sir Woodman is going to Buenos Aires on business, and considers that the saving of fourteen days on the journey will be worth the increase in fare, which he understands will be between $2,000 and $2,500 for one way. Aerial mail will be carried at special rates, and will be able to compete with cable communication in cheapness but in speed of transmission.

He will take his wife with him, and he believes that there will be other women passengers. The total number of passengers, he says, will be about fifteen.

As at present arranged there will be two stopping places—one in Spain and one in Brazil.

Postmarks On Air Mail

OFFICE FIRST ASSISTANT
POSTMASTER GENERAL,
Washington, January 17, 1919.

It has been brought to the attention of the department that many postmasters use ordinary rubber hand stamps and various colored inks in postmarking mail received for dispatch by Aeroplane Service. This practice will be discontinued immediately, and all aeroplane mail will be postmarked and the stamps thereon canceled by the use of canceling machines or the regular hand postmarking stamps, and the black canceling ink furnished by the department for such purpose.

J. C. KOONS,
First Assistant Postmaster General.

Second Assistant Postmaster Otto Praeger, in charge of the Aero Mail, who is doing excellent work in the development of this service

More R. M. A.'s

The following officers have been rated as Reserve Military Aviators: 1st Lieut. Carl B. Fry, A. S. A.; 2nd Lieut. William E. Vogelback, A. S. A.; 2nd Lieut. Frederick H. Winston, A. S. A.; 2nd Lieut. Francis J. Winter, A. S. A.; 2nd Lieut. Claude R. Conklin, A. S. (M. A.); 2nd Lieut. Douglas M. Fraser, A. S. (M. A.); 2nd Lieut. Francis Jordan Winter, A. S. (M. A.); 2nd Lieut. Walter Lee Isom, A. S. (M. A.); 2nd Lieut. J. O. Stoddart, A. S. (M. A.); Captain Sylvanus C. Coon, A. S. A.; 1st Lieut. Adam Truello, A. S. A.; 2nd Lieut. Marston Campbell, Jr., A. S. A.

Air Service Units En Route Home

The Battleship New Jersey sailed from Brest January 15th and is due at Newport News January 27th, with the following troops: 480th Aero Squadron, Camp Meade, 4 officers, 152 men; 481st Aero Squadron, Ft. Slocum, 3 officers, 154 men.

The Cruiser Frederick sailed from Brest January 17th and is due at New York January 29th with the following troops: 466th Aero Squadron, Regular Army, 4 officers, 153 men; 492nd Aero Squadron, Camp Meade, 2 officers, 152 men.

The Battleship Connecticut sailed from Brest January 20th and is due at Newport News February 1st with the following troops: 162nd Aero Squadron, Camp Meade, 2 officers, 148 men; 490th Aero Squadron, Camp Meade, 4 officers, 151 men.

Following organizations have been assigned to early convoy: 90th Aero Squadron, 24 officers, 148 men; 104th Aero Squadron, 10 officers, 176 men; 17th Balloon Co., 9 officers, 174 men; 18th Balloon Co., 8 officers, 174 men; 11th Aero Squadron, 20th Aero Squadron, 161st Aero Squadron, 169th Aero Squadron, 248th Aero Squadron, 655th Aero Squadron, 656th Aero Squadron, 487th Aero Squadron, 494th Aero Squadron, and Air Service Casual Co. No. 3.

OTTO PRAEGER, Second Assistant Postmaster General.

Instruments and knowledge of how to use them are absolutely necessary to success in cross-country flying

INSTRUMENTS FOR CROSS COUNTRY FLYING

By T. A. MORGAN, Sperry Gyroscope Co.

THE first essential for a long cross country flight such as is now being attempted by the Mail Service is an accurate compass. Such an instrument has been developed for the U. S. Navy and is known as the Navy Standard No. 1 Aircraft Compass. Quantities of these are available at the present moment.

To be of value the compass must be properly installed and properly compensated. It must be mounted so that it is free from violent vibration. The Navy Standard No. 1 compass is designed to be held down securely. If mounted rigidly to a part of the aeroplane it will function properly. A machine recently flew from Akron, Ohio, to Washington, D. C., entirely by this compass with a final error of only 8 miles.

The compensation of a compass is of great importance. The motor and other masses of metal disturb the earth's magnetic field, so that magnets must be placed near the compass to restore it to the North position. The compensation of the compass must be checked at frequent intervals as the magnetism of the plane is continually changing. If the compass is mounted near a Liberty engine ignition switch (which should always be avoided, if possible) it must be compensated with the ignition circuit closed.

It is seldom possible to completely compensate a compass and resulting errors should be noted on a chart beside the compass. An error of 5 or 6 degrees will often remain on some headings, and this error, if not taken into account, would take a man 40 miles off his course on a 500 mile flight.

In navigation by compass, account must be taken of the variation of the compass. This is the amount that the needle points east or west of true north. As variation varies for different parts of the country it is especially necessary to figure on it on long flights. For instance, the variation at Chicago is 2½° East and at New York is 10½° West. If a man flying from New York to Chicago should neglect this error he would miss Chicago by 50 miles.

Another factor which must be carefully considered in navigating the air is drift. That is, the difference between the heading of a machine and the course actually travelled, the difference being due to the wind.

A pilot flying from New York to Chicago failing to take account of a North wind of only 10 miles an hour intensity would be blown 60 miles off his course, even if he used a 120 mile an hour De Haviland 4 aeroplane. The "drift" must therefore be carefully taken into account. There are instruments on the market which enable the pilot to automatically correct for it.

An air speed indicator must be used to enable the pilot to tell how fast he is going, and knowing this, to judge his distance. As many air speed indicators in common use are found to be from 10 to 30 miles an hour wrong, the calibration of this instrument must also be taken into account. The use of an air distance recorder which, independently of the air speed indicator, shows the pilot the exact number of air miles travelled, is a great assistance.

In fog or clouds the difficulties of aerial navigation are tremendously multiplied and as much flying, such as in the Mail Service, must go on regardless of weather, other instruments are necessary. When it is not possible to see the earth it is very difficult to keep a plane on a straight course, even with the aid of a compass, as all pilots know who have done any flying in bad weather. Once a turn is started the compass is of no value, and much time is lost in straightening out again, if more serious trouble is not encountered. A turn indicator is therefore necessary to advise the pilot instantly of any divergence from his course.

For long flights under bad conditions, a directional stabilizer becomes a necessity as the mental and physical strain on the pilot is completely removed by this apparatus, which takes complete automatic control of the ship's rudder.

A complete automatic aeroplane control is also entirely practical and should be used on large planes.

The Air Mail Service, judging from the lack of results, so far, on the Chicago-New York route, is failing to appreciate the necessity of the instruments and of the proper care of those in use.

THE CURTISS MODEL K-6 AND K-12 AERO MOTORS

IN the design of Curtiss K-6 and K-12 motors, the form of construction adopted gives a minimum centre distance between cylinders, together with careful placing of the accessories, makes the motor compact and easily placed in the fuselage, at the same time the accessibility of the varions parts is such that sub-unit may be readily inspected or overhauled without disturbing the motor in the aeroplane.

Gear Reduction

The gear reduction of the Model K-12 raises the centre of thrust to a point near the centre of gravity, and close to the centre of projected area. This enables the design of the nacelle or fuselage to be reduced in size, with consequent lower head resistance.

Efficiency

This gear reduction enables high piston speeds to be maintained, which, with the motor's normal high mean effective pressure, increases the power output without increasing the propeller R. P. M. above a normal figure. As a slow speed propeller is 5 per cent to 7 per cent more efficient than a high speed propeller, the geared down motor will deliver a greater net power per pound of gasoline, consequently the overall efficiency is greater.

Crank Case

The design of the crank case, coat of alloy aluminum is such that, due to the cylinder water jackets being integral, extreme rigidity and absolute alignment of parts are maintained, as well as an appreciable saving in lightness gained. The lower half, containing the oil pan is securely bolted to the flange on the centre line of the crank shaft, which also adds to the stiffness of the assembly.

Reduction Gears

The reduction gears of the K-12 are forged from alloy steel. These are rough lanked and cut. The teeth are 5-7 pitch, Fellow's stub tooth form, the teeth staggered, one inch width of face per side. After heat reatment, the centres and faces are ground, and the gears are then recut to insure accuracy and high mechanical efficiency in operations. The standard reduction is from five revolutions of the engine to three of the propeller shaft.

Propeller Shaft

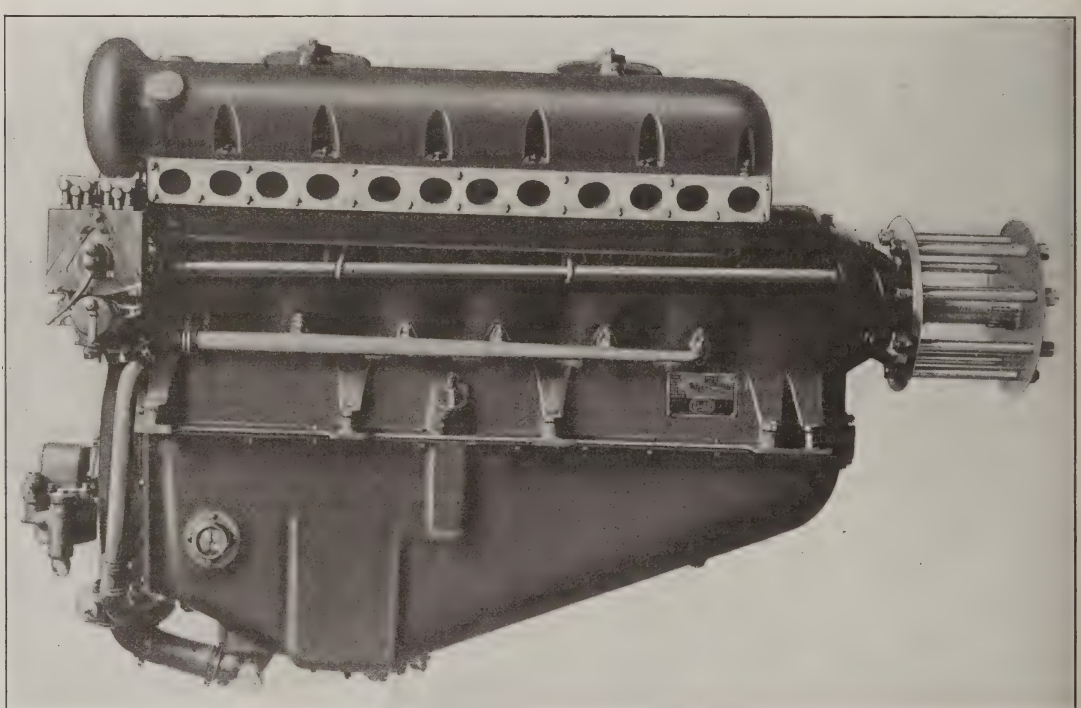
The propeller shaft of the K-12 is made of the same material, and with the same care as the crankshaft. It carries the reduction gear, and the ample grooved plate type thrust bearings, which are mounted to take thrust in both directions.

The front flange for the propeller is machined integrally with this shaft, the flange is drilled for eight bolts, the bolts themselves remaining in the propeller, and are centered by conical split washers. By this system of mounting the propeller is at all times held firmly in place, but the disadvantages of the taper fit hub are done away with and greater lightness secured.

Cylinders

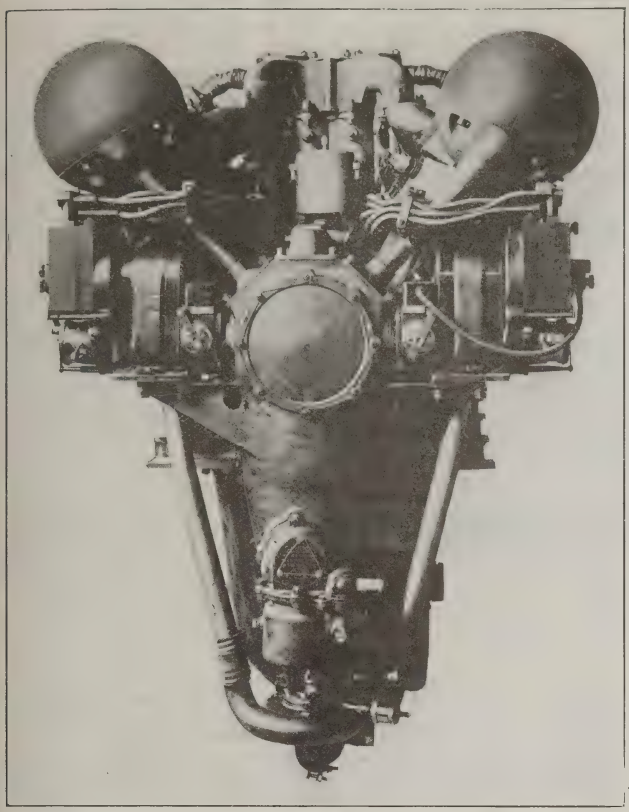
The cylinders are rough machined from a special analysis hydraulic steel forging, heat treated and finished machined all over, with the cylinder head forged integral. This type of cylinder insures maximum strength with minimum weight, the water being in direct contact gives uniform efficient cooling with minimum cylinder distortion.

Connecting Rods



The connecting rods are forged from specially selected steel and are carefully heat treated. The rods are machined all over, and are held to the most accurate limits possible as to size. The finished rods are carefully balanced as to weight, not only with each other as a whole, but as to each end.

Crank Shaft



Each crank-shaft has a test piece taken off which goes to the Curtiss laboratories, where all its characteristics are determined to insure that each forging is up to specifications before any machining is started. The inspection of the finished shaft comprises a a minute inspection for checks or surface flaws, a static balance test and finally a running balance test. This care, in producing the shafts coupled with the high grade steel used, and the large dimensions of the shaft itself, insure a product which will stand up indefinitely under the severest strains. The crank-shaft is tapered and keyed to receive the propeller hub, which is drawn tight with a differential thread nut at end of shaft.

Bearings

The Curtiss practice of reaming instead of hand scraping the crank-shaft and connecting rod bearings eliminates the variations that are unavoidable when this is done by hand, and permits replacements without any fitting, as both the inside and the outside diameters of the bearings are held so close in manufacture that new ones will drop more accurately in place than would be possible to fit them by hand.

Side view of the Curtiss Model K-12 aviation motor

Anti-propeller end of the Curtiss Model K-12 aviation motor

Valve Gear

The new valve gear used on the K-12 motor is a distinct advance over previous motors. The light cam follower relieves the valves of any side strains due to cam action, and provides means of easy adjustment of clearance. As the cam shafts are directly over the valves, all rocker arms, push rods, etc., are done away with and the whole assembly is absolutely oil tight.

Ignition

Double ignition, from the two separte magnetos gives a more instantaneous explosion, which at high engine speed is necessary to develop high mean effective pressures. The spark plugs are located near the intake valves, on the upper side, to guard against fouling and insure absolute ignition. The wire assemblies are enclosed in insulating covers of micarta, which guard against short circuit and injury.

Carburetion

A duplex carbureter (K-12 is provided with two carburetors), each tube supplying one set of three cylinders, assures a more satisfactory charge than a single carbureter equipment, due to the separate manifolds which prevent starving and eddying, and the better vaporizing properties of two small carburetors over one large one. In addition, hot water jackets are provided on the manifolds to assist in vaporizing the gasoline.

Lubrication

Pressure feed through crank shaft, propeller shaft and cam shafts, insures a continual film of clean oil on all bearings. Separate return pump with double intake absolutely prevents accumulation of oil in either end of pan, and consequent flooding of cylinders when machine is climbing or gliding. Pressure adjustment permits of individual adequacy of oil feed on each motor, and change for wear and varying conditions of service.

Bolts and Nuts

All bolts and nuts on Curtiss Motors are made from special steel, must be of specified hardness according to sclerescope test, all threads must be accurate to standard gauge. Every nut is either cotter pinned, lock washered, or safety wired in series.

Inspection

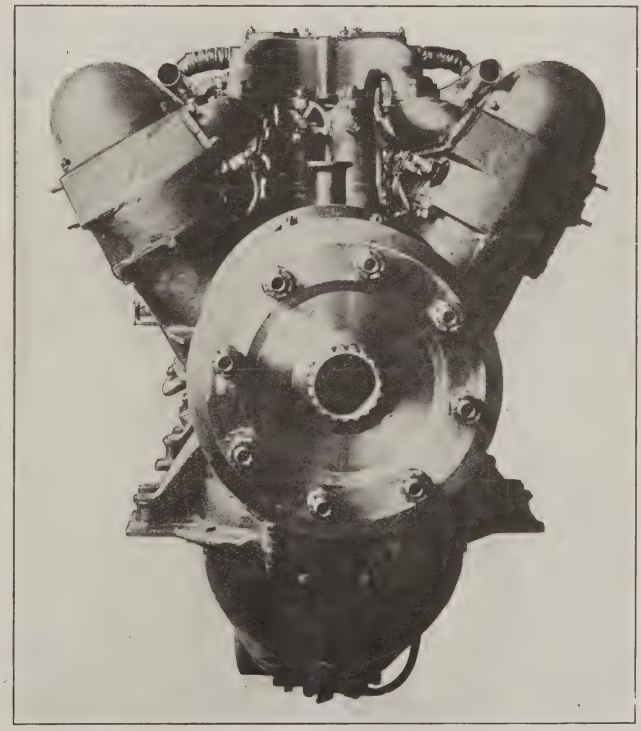
Thirteen percent of the labor expense in the Curtiss motor plant is for inspection. Inspection that starts with the composition of raw materials, and follows intimately through all the stages of heat treating, machining, assembling, testing and even shipping.

Type of Motor

K-6 is a six-cylinder water cooled—cylinders en bloc—aluminum construction. K-12 is a 12-cylinder motor with a 5 : 3 gear reduction to propeller shaft.

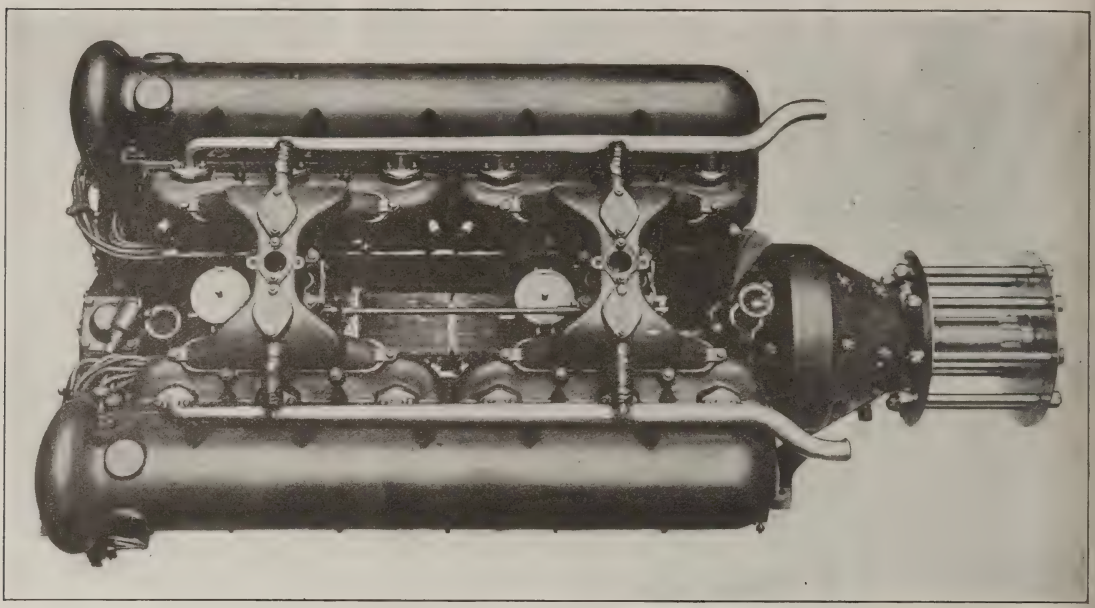
Horse Power

K-6 rated at 150 H.P. at 1,700 R.P.M. K-12 rated at 375 H.P. at 2,250 R.P.M. at crankshaft.



Bore and Stroke

4½″ x 6″.



Weights (Lbs.)	Model K6	Model K12
Cooling Water in Motor	—	38
Basic Motor	346	589
Carburetor and Intake Manifold	18	37
Ignition Equipment	32	37
Water Inlet Lines	4	4
Exhaust Manifold	14	28
Hand Starting Crank	3	—

Gasoline Consumption

Fifty-five lbs. per H.P. Hour.

Propeller end of the Curtiss Model K-12 aviation motor

Top view of the Curtiss Model K-12 aviation motor

Ignition

Two high tension six cylinder magnetos complete with spark plugs and wire assembly. Magnetos are located at front end of motor, and driven by bevel gears from vertical shaft through flexible couplings.

Carburetion

Duplex type automatic carburetor located right hand side of cylinder group. K-12 equipped with two duplex carburetors located between the cylinder groups. Auxiliary altitude air valve, hand controlled. Non-backfiring screen connecting air horns.

Lubrication

Adjustable pressure feed—the oil is forced from reservoir in bottom of crank case by gear pump to oil distributing tube, from whence it is fed to each main bearing on the crank shaft, hence through tubes to each connecting rod bearing.

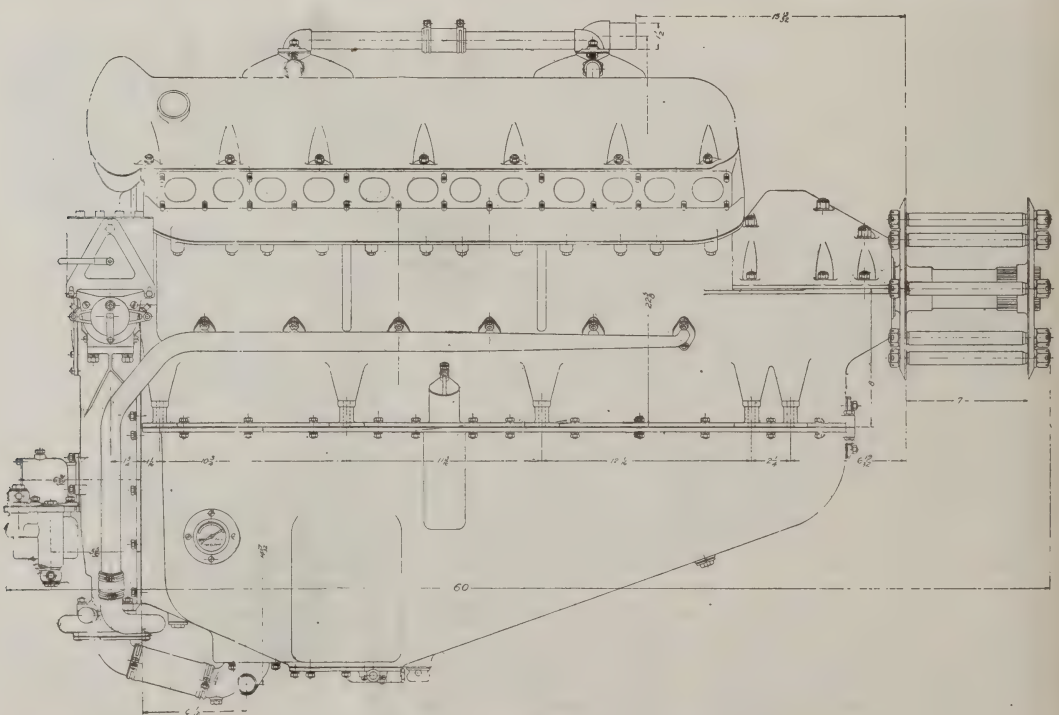


Diagram side view of the Curtiss Model K-12 aviation motor

The pistons and piston pins are fed by spray from connecting rod bearings. At the front main bearings the oil is led up to the hollow cam shafts, circulating through them, and lubricating all the bearings, followers, etc. Gravity return to imperforate splash pan. Return to reservoir by a duplex gear pump with oil leads to both ends of oil pan which prevents flooding when motor is out of horizontal position. Both oil pumps are located inside a large screen on plate on bottom of crank case, removable for inspection and cleaning purposes, and are driven by bevel and helical gears from the vertical shaft. Oil pressure adjustment valve located on outside of removable plate.

Water Circulation

Centrifugal pump. Water is introduced at bottom of each cylinder, is forced through cylinders and intake manifold, thence back to radiator. Water pump is bolted to lower end of gear case at front of motor, and is driven by flexible coupling from vertical shaft.

Cylinders

Steel forgings, machined all over. Top of cylinder threaded and screwed into cylinder head casting, six forming a complete assembly. Cylinder wall ribbed for strength. Cylinder head assembly bolted to crank case which forms water jacket around cylinder sleeves.

Valves

Poppet type in head, two intake and two exhaust per cylinder valves—Tungsten steel. All valves 1⅝" diameter at throat.

Valve Springs

Concentric coil type, alloy steel.

Cam Followers

Tee type, having valve clearance adjustments at ends, bearing surface in center working in cast iron bushing. Wearing surfaces case hardened and ground.

Camshafts

Drop forged with interal cams, separate shafts for inlet and exhaust valves, each pair of valves having one cam, cams case hardened. Six bearings. Finish ground all over.

Camshaft Bearing

Bracket and cap type aluminum bolted to top of cylinder head.

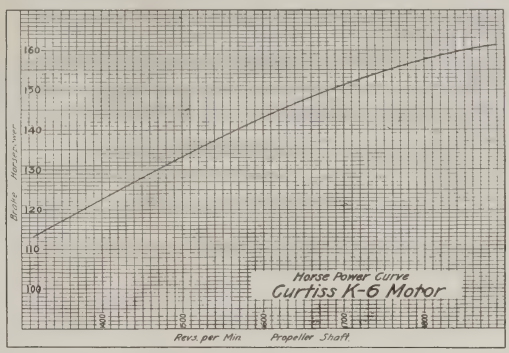
Pistons

Aluminum alloy castings, flat head type. Piston pin bearings in piston without bushings. Three concentric cast iron rings.

Piston Pins

Alloy steel, drilled hollow, case hardened and ground. Pins float in pistons and connecting rods and constrained from end motion by two snap rings in piston.

Connecting Rods



Alloy steel, I-Beam type forgings machined all over.

Connecting Rod Bearings

Main special bearing metal—bronze backed, reamed to running clearance of exact size of crank pin. Held in rod by four brass screws. Ribbed formation at sides to retain oil. Steel cap bolted to rod with four bolts. Piston pin bushings, Non-Gran bronze, drive fit in rods.

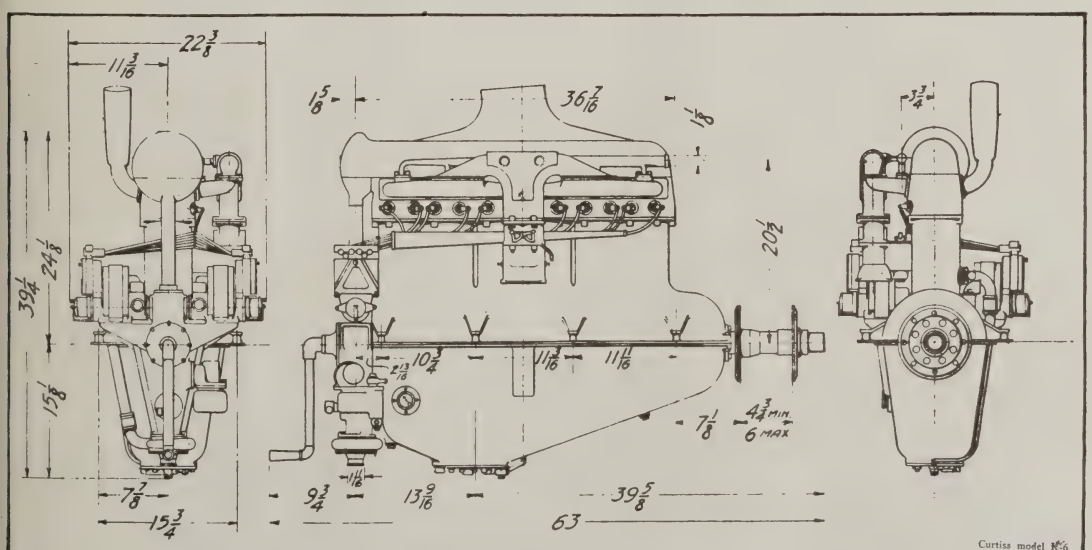
Crankshaft

Highest grade alloy steel, finished all over and drilled hollow. All bearings ground. Pins and main bearings 2½" dia. 6 throw, 5 main bearings. End of shaft tapered and fitted with key for propeller hub.

Crankshaft Bearings

Special bearing metal—bronze backed. Reamed to running clearance of exact size of crank shaft.

Propeller Shaft



On the K-12 the propeller shaft is of the highest grade alloy steel—finished all over, drilled through. Rear flange of propeller integral with shaft. Flanged for reduction gear. Large isze ball thrust bearings to take thrust as tractor or pusher without change. Propeller shaft mounted in ribbed cap taking thrust bearings and special bearing metal bushings.

Reduction Gears

Reduction gears on the K-12 are forged from alloy steel. Cut 5-7 staggered herring bone, standard reduction 5 to 3. Gears bolted to flanges with alloy steel bolts.

Propeller Thrust Bearing

On the K-6, large deep race annual rbearings arranged to take thrust in either direction mounted between two rear crankshaft bearings.

Anti-propeller end, side, propeller end diagrams of the Curtiss K-6 aero motor

Crank Case

Aluminum alloy castings—bearings in heavily ribbed diaphragms. Eight motor supporting arms—casting extends up to form water cylinder jackets integrally with crank case.

Timing Gears

Cam shafts and accessories driven from vertical shaft by bevels. Bevel drive between crank shaft and vertical shaft. All bevel gears alloy steel, heat treated, and flanged, splined, or integral to shafts.

Magneto Drive

Bevel drive from vertical shaft, running in Annular S.K.F. Bearings contained in removable housing. Flexible coupling between magnetos and gears.

Water Pump

Centrifugal type—cast aluminum housing and blades, coupled to vertical shaft. Bolted to lower face of front gear case.

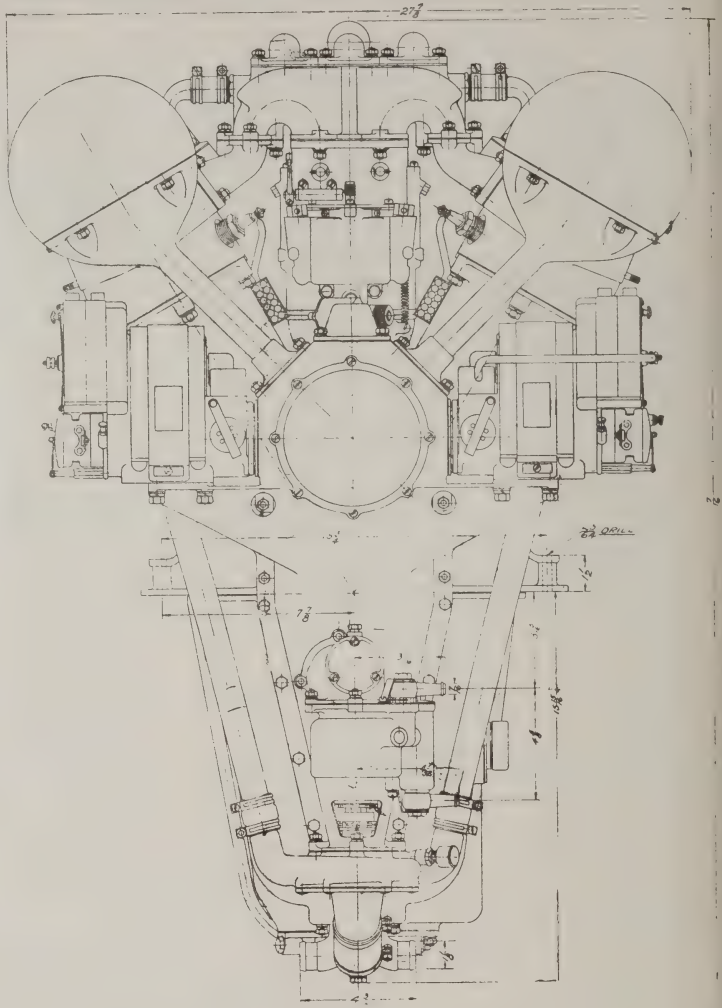
Tachometer Drive

Shaft gear in aluminum housing driven vertical shaft.

Intake Manifold

Aluminum castings—water jacketed.

Exhaust Manifold



Shee steel, collector type, carrying exhaust gases upward.

Water Piping

Steel tubing, nickel plated inside and out. Rubber hose connections. All cylinder nipples flanged and bolted.

Bolts, Nuts, Etc.

All bolts and nuts alloy steel. Heat treated. All locked with cotter pins on interior, lockwashers on exterior.

Section design Curtiss Model K-12 aviation motor

Appointments in Bureau of Aircraft Production

Washington, Jan. 17.—Lt. Col. R. M. Jones, A. S., A. P., has been appointed Assistant and Executive Officer to the Acting Director of Aircraft Production. In addition to his present duties as Executive Officer, he will also be charged with such activities as pertain to liaison, correspondence with the War Department and other departments or bureaus of the government.

Lt. Col. H. C. Clark, A. S., A. P., in addition to his other duties, will take over the duties of adviser and assistant to the Acting Director on matters pertaining to personnel for the bureau.

Lt. Col. O. Westover, A. S., A. P., is appointed assistant to the Acting Director of Aircraft Production.

Major George F. Lyons, A. S., A. P., is appointed assistant to the Acting Director of Aircraft Production.

Personal Pars

C. H. Smith has recently joined the A. B. C. Casting Co., Cleveland, to take charge of its aluminum forging development work. He was formerly with the Driggs-Seabury Ordnance Corp. and later with the Ladish Forge Co., Cudahy.

F. W. Sutton, formerly production manager of the Continental Motors Corp., and later general superintendent of the Dayton-Wright Airplane Co., is now the chief engineer of the Charles E. Dedeaux Co., industrial engineers, with headquarters in Cleveland.

Peace Delegates' Planes Carry Radiophones

London, Jan. 25.—The aeroplanes which are carrying the Peace Conference delegates and important documents between London and Paris are equipped with wireless telephone apparatus. This enables the pilots to speak to one another while in the air and also enables them to receive frequent weather reports and instructions from the ground.

The Standard Mail Aeroplane

(*Continued from page* 1036)

both wings, 5.2, when overhang section is not used.

Tops of center section struts are spaced 32¾" from center to center. Middle struts 5'–8" from center section struts; outer struts 6'–3" from middle struts. This leaves an overhang of 33½".

When overhang section is used, top of inclined struts are centered 4'–8½" from outer struts, leaving an overhang of 22½".

The "Spad" truss is used between the planes, having a steel tube compression member between front and rear middle struts, where flying and landing cables cross.

Fuselage

The engine is carried on a pyramid type support.

Mail is carried in a compartment situated at the center of gravity, just forward of the pilot's cockpit.

When the machine is at rest, the propeller axis is 6'-0" above ground; in flying position it is 5'–0" above ground. In flying position, a line from wheel base to center of gravity makes a 14° angle with a vertical line.

Angie between line joining wheel base and skid to a horizontal line, 11 degrees—30 minutes.

The stabilizer is fixed at a neutral angle.

Landing Gear

The usual two-wheel landing gear is used, but provision is made for the attachment of a third wheel, as shown in the drawing, which adds 25 lbs. to the weight.

Steel tube is used for chassis members, faired with spruce streamline stiffening pieces.

Engine Group

The engine is a Wright-Martin Model I Hispano-Suiza, giving 150 H.P. at 1,500 r.p.m. and 170 H.P. at 1,700 r.p.m. A detailed description of the Hispano-Suiza appeared in the December 30, 1918, issue of Aerial Age.

The model I is an 8 cylinder V type with a bore of 120 mm (4.724") and a stroke of 130 mm (5.118"). Zenith Carburetor and magneto ignition are used.

Engine weight, with propeller, 455 lbs. Propeller, 9'-0" in diameter.

Fuel consumption, 0.51 lbs. per h. p. per hour; oil consumption, 0.03 lbs. per h. p. per hour. Fuel tanks are located at the center of gravity; their capacity is 60 gallons. Oil tanks located underneath the engine; capacity, 4 gallons.

The nose radiator is of the Livingston type. Water capacity, 9 gallons.

CITATIONS FOR BRAVERY

SECOND LIEUTENANT CHARLES P. PORTER, pilot, Air Service, 147th Aero Squadron. For extraordinary heroism in action in the region of Epips, France, July 16, 1918. While on patrol Lieutenant Porter observed two enemy planes (Fokker type) about 1,000 metres above him. He immediately manœuvred to obtain height and a position for attack. The enemy turned and Lieutenant Porter gave chase and attacked from below, destroying one and forcing the other to retire. A bronze oak leaf for extraordinary heroism in action in the region of Forest de Fere, France, July 24, 1918. Lieutenant Porter, while leading a patrol, attached an enemy formation of twelve planes (Fokker type). He engaged one enemy and sent it down out of control. One of Lieutenant Porter's guns jammed, and while he was repairing the gun two of the enemy planes got behind him. Unable to repair the gun and only to fire a single shot, he turned to attack, destroying a second plane and remained in the fight until the enemy retired. Home address: Charles S. Porter, father, 121 to 131 West Twenty-seventh street, New York City, N. Y.

First Lieutenant Leslie J. Rummell, Air Service, Ninety-third Aero Squadron. For extraordinary heroism in action in the region of Mosery, France, September 29, 1918. Lieutenant Rummell, leading a patrol of three planes, sighted an enemy biplane, which was protected by seven machines (Fokker type). Despite the tremendous odds he led his patrol to the attack and destroyed the Di Nash plane. By his superior manœuvring and leadership four more of the enemy planes were destroyed and the remaining three retired. Home address: Alfred T. Rummell, brother, Pennington and Johnson streets, Newark, N. J.

First Lieutenant William H. Stovall, pilot, Air Service, Thirteenth Aero Squadron. For extraordinary heroism in action in the region of Etain, France, September 26, 1918. While leading a protection patrol over a day-bombing formation, Lieutenant Stovall's patrol became reduced, through motor trouble, to himself and one other pilot. When the bombing patrol was attacked by seven enemy planes, Lieutenant Stovall in turn attacked the enemy and destroyed one plane. Home address: Mrs. William H. Stovall, mother, Stovall, Miss.

First Lieutenant Alfred B. Patterson, Jr., pilot, Air Service, Ninety-third Aero Squadron (deceased). For extraordinary heroism in action in the region of Moiery, France, September 29, 1918. Lieutenant Patterson, while on a patrol with two other machines, attacked an enemy formation of seven planes (Fokker type) that were protecting a biplace plane. They destroyed the biplane and four of the Fokkers, forcing the remaining three to retire. A bronze oak leaf for extraordinary heroism in action in the region of Moiery, France, October 23, 1918. Lieutenant Patterson led a formation for the purpose of protecting our bombing planes, the accompanying planes being obliged to return, due to engine trouble. Despite this fact, Lieutenant Patterson proceeded on the mission alone. He sighted an enemy patrol of nine machines (Fokker type) and attacked them, driving one down. Home address: A. B. Patterson, father, 438 Franklin avenue, Wilkinsburg, Pa.

First Lieutenant Charles E. Wright, pilot, Air Service, Ninety-third Aero Squadron. For extraordinary heroism in action near Keffu, France, in October, 1918. Lientenant Wright attacked an enemy observation balloon protected by four enemy planes and, despite numerical superiority, he forced the planes to withdraw and destroyed the enemy balloon. A bronze oak leaf, for extraordinary heroism in action near Bantheville, France, October 23, 1918. Lieutenant Wright, accompanied by one other machine, attacked and sent down in flames an enemy plane (Fokker type) that was attacking an Allied plane. He was in turn attacked by three enemy planes. His companion was forced to withdraw on account of motor trouble. Lieutenant Wright continued the combat and succeeded in bringing down one of the enemy planes and forced the remaining two into their own territory. Home address: Mrs. R. W. Wright, mother, 131 Southerland road, Brookline, Mass.

Major Lewis H. Brereton, pilot, corps observation wing. For extraordinary heroism in action over Thiaucourt, France. Major Brereton, together with an observer, voluntarily, and pursuant to a request for special mission, left his airdrome, crossed the enemy lines over Lironville, and proceeded to Thiaucourt. In spite of poor visibility, which forced them to fly at a very low altitude, and in spite of intense and accurate antiaircraft fire they thaintained their flight along their course and obtained valuable information. Over Thiaucourt they were suddenly attacked by four enemy monoplane Fokkers. Maneuvering his machine so that his observer could obtain a good field of fire, he entered into combat. His observer's guns becoming jammed, he withdrew until the jam was cleared, when he returned to the combat. His observer then becoming wounded, he cooly made a landing within friendly lines, although followed down by the enemy to within 25 meters of the ground. By this act he made himself an inspiration and example to all the members of his command. Home address, Mrs. Lewis H. Brereton, wife, Ontario Apartments, Washington, D. C.

Second Lieutenant Elmer K. McKay, Air Service, observer, 96th Aero Squadron. For extraordinary heroism in action near Dun-Sur-Meuse, France, October 23, 1918. Lieutenant McKay, with First Lieutenant Harry O. McDougall, pilot, while on a bombing mission displayed exceptional courage by leaving a comparatively secure position in the center of the formation during a combat with five enemy planes and going to the protection of two other officers whose planes had been disabled and forced out of the formation. While his pilot skilfully maneuvered the machine, Lieutenant McKay shot down one of the adversaries and fought off the others, thereby saving the lives of the officers in the disabled American plane. Home, address, James D. McKay, father, 817 Eleventh Street N. E., Washington, D. C.

First Lieutenant Harry O. McDougall, Air Service, pilot, 96th Aero Squadron. For extraordinary heroism in action near Dun-Sur-Meuse, France, October 23, 1918. Lieutenant McDougall, with Second Lieutenant Elmer McKay, observer, while on a bombing mission, displayed exceptional courage by leaving a comparatively secure position in the center of the formation during a combat with five enemy planes and going to the protection of two other officers whose planes had been disabled and forced out of the formation. Lieutenant McDougall skilfully maneuvered his machine so as to enable Lieutenant McKay to shoot down one of the adversaries and fight off the others. Home address, D. C. DcDougall, father, 132 South Hayes Street, Pocatello, Idaho.

Lieutenant Kingman Douglass, Air Service, pilot, 91th Aero Squadron. For extraordinary heroism in action near Longuyon, October 31, 1918. While on a photographic mission Lieutenant Douglass encountered a superior number of enemy pursuit planes. Notwithstanding the odds against him, he turned and dived on the hostile formation, destroying one plane and damaging another. He then continued on his mission and returned photographs of great military value. Home address, W. A. Douglass, 317 North Kenilworth Avenue, Oak Park, Ill.

First Lieutenant Ora R. McMurry, American Expeditionary Forces, 49th Aero Squadron. For extraordinary heroism in action near Ormagne, France, October 4, 1918. Lieutenant McMurry was a member of a patrol of 7 machines which attacked 17 enemy Fokkers. After shooting down one of the enemy, this officer returned to the fight and shot down another. Home address, Mrs. J. C. McMurry, mother, Evansville, Wis.

First Lieutenant Lewis C. Plush, Air Service, 49th Aero Squadron. For extraordinary heroism in action near Romagne, France, October 4, 1918. Lieutenant Plush was a member of a patrol of 7 machines which attacked 17 enemy Fokkers. After shooting down one of the enemy, this officer returned to the fight and shot down another. Home address, William Plush, father, 440 East Phillips Boulevard, Pomona, Cal.

Captain Walter R. Lanson, Air Service, observer, 91st Aero Squadron. For repeated acts of extraordinary heroism in action near St. Mihiel, France, July 30 and September 13, 1918. This officer showed rare courage on a reconnaissance far over the enemy lines, when he continued on his mission after being seriously wounded by anti-aircraft fire. On September 13, although he was still convalescing from his wound, he volunteered for a particularly dangerous mission requiring a flight of 75 kilometers within the enemy lines. Because of weather conditions he was forced to fly at a dangerously low altitude and was repeatedly fired on by anti-aircraft and machine guns. He successfully accomplished his mission and returned with important information. Home address, Mrs. W. R. Lasson, wife, Birmingham, Ala.

First Lieutenant Harvey Conover, Air Service, pilot, 3d Observation group. Deceased. For extraordinary heroism in action near Consenvoye, France, October 27, 1918. Flying at an altitude of less than 50 meters over enemy artillery and machine guns, which were constantly firing on him, Lieutenant Conover and his observer staked the American front lines and gave valuable information and assistance to the advancing infantry. Although suffering from two severe wounds, and with a seriously damaged plane, he delivered a harassing fire on six enemy machine-gun nests which were checking the advance of the ground troops, and successfully drove off the crews of four guns and silenced the other two. He then made a safe landing and forwarded his information to division headquarters before seeking medical aid. Home address, L. P. Conover, father, Hinsdale, Ill.

First Lieutenant Benjamin P. Harwood, Field Artillery, Air Service. For extraordinary heroism in action near Chateau-Thierry, France, July 5, 1918. Lieutenant Harwood volunteered with another plane to protect a photograph plane. In the course of their mission they were attacked by seven enemy planes (Fokker type). Lieutenant Harwood accepted the combat and kept the enemy engaged while the photographic plane completed its mission. His guns jammed and he himself was seriously wounded. After skilfully clearing his guns, with his plane badly damaged, he fought off the hostile planes and enabled the photographic plane to return to our lines with valuable information. Home address, E. N. Harwood, father, Billings, Mont.

First Lieutenant Leo C. Ferrenbach, Air Service. For extraordinary heroism in action near Ansauville, France, July 22, 1918. Lieutenant Ferrenbach, a balloon observer, was conducting an important surveillance of his sector when at an altitude of 800 meters successive attacks were made upon the balloon by enemy planes. This officer refused to leave his post and continued his work with strong enemy patrols hovering above him until one of the hostil machines dived and set fire to the balloon. After he had jumped in his parachute, the burning balloon fell and barely missed him. Lieutenant Ferrenbach immediately reascended while enemy patrols were still in the vicinity. Home address, Edward J. Ferrenbach, father, 5441 Bartmer Avenue, St. Louis, Mo.

First Lieutenant J. A. Higgs, Air Service. For repeated acts of extraordinary heroism in action near Pont-a-Mousson, France, July 31 and August 21, 1918, near Gesnes, France, October 29, 1918. On July 31, near Pont-a-Mousson, Lieutenant Higgs was carrying on a general surveillance of his sector from his balloon with a French soldier, when an enemy plane dived from a cloud and opened fire on the balloon. In imminent danger he remained in basket until he had helped his French comrade, after whom he himself jumped. On August 21, in the same sector, Lieutenant Higgs was performing an important mission regulating artillery fire. Enemy planes attacked, and with great gallantry Lieut. Higgs remained in the basket until his assistant had jumped. On October 29, near Gesnes, Lieutenant Higgs was conducting a reglage from the basket with a student observer. Attacked by enemy planes, after his balloon was burning, Lieutenant Higgs would not quit his post until he had assisted his companion to escape. In each of the foregoing instances, Lieutenant Higgs at once reascended in a new balloon. Home address, Mrs. James A. Higgs, wife, Lathrop, Pickens County, Ala.

Second Lieutenant Cleveland W. McDermott, Air Service, 147th Aero Squadron. For extraordinary heroism in action near Bantheville, France, October 18, 1918. In starting on a patrol mission Lieutenant McDermott was delayed by motor trouble. Unable to overtake the other machines, he continued on alone. Sighting an enemy Fokker, he immediately gave chase, and despite its effort to escape, succeeded in shooting it down. Six Fokkers then suddenly attacked him, and though he was outnumbered and blinded by the sun, he shot down one of them and scattered the others. In the midst of this combat his motor stopped, and he was forced to glide into friendly territory. Home address, John McDermott, father, 209 Jackson Street, Syracuse, N. Y.

First Lieutenant Cleo J. Ross, deceased, Air Service, for extraordinary heroism in action near Brabant, France, September 26, 1918. Lieutenant Ross was engaged in an important observation, regulating artillery fire, when his balloon was attacked by enemy planes. One of the planes dived from a cloud and fired at the balloon, setting fire to it, and though he could have jumped from the basket at once he refused to leave until his companion, a student observer, had jumped. Lieutenant Ross then leaped, but it was too late, for the burning balloon dropped on his parachute. He was dashed to the ground from a height of 300 meters and killed instantly. Next of kin, E. M. Ross, father, Titusville, Pa.

First Lieutenant Ralph O'Neill, Air Service, pilot, 147th Aero Squadron, for the following act of extraordinary heroism in action near Fresned, France, July 24, 1918. A bronze oak loaf is awarded to Lieutenant O'Neill, to be worn on the distinguished service cross awarded to him October 12, 1918. Lieutenant O'Neill, with four other pilots, engaged 12 enemy planes discovered hiding in the sun. Leading the way to an advantageous position by a series of bold and skillful maneuvers, Lieutenant O'Neill shot down the leader of the hostile formation. The other German planes then closed in on him, but he climbed to a position of vantage above them and returned to the fight and drove down another plane. In this encounter he not only defeated his opponents in spite of overwhelming odds against him, but also enabled the reconnaissance plane to carry on its work unmolested. Home address, Mrs. R. L. O'Neill, mother, 218 Sonoita Street, Nogales, Ariz.

THE STANDARD MODEL E-4 MAIL AEROPLANE

MAIL is now carried between New York and Washington in the specially built "E-4" mail machine brought out by the Standard Aero Corporation. Other air mail routes contemplate the use of the "E-4", because of the special features of its design, and particular adaptability to the work.

For winter flying, overhang extensions are attached to the ends of upper wings, increasing the span from 31'-4¾" to 39'-8¾".

he Hispano-Suiza Engine

HISPANO-SUIZA developed its world-wide reputation during the early stages of the Great War.

The very peak of its efficiency was ached when the Air Forces of France id England were gaining that now well- derstood "Air Supremacy" at the end of e second year of the Struggle. It was en that France's most noted aces, Guy- mer, Fonck, Herteaux and others were tablishing their marvelous records in the nall, swift, deadly one-seater planes— e "Spads"—which were made possible ly because of the speed, flexibility and rsatility of the Hispano-Suiza Engine.

Since then, in the powering of the one aters, the two and three seaters, and the eavier bombing machines and hydro-planes, Hispano-Suiza has kept pace with the development of the aeronautical activities of several nations. Hispano-Suiza has reached that point of efficiency which would have been impossible, except where a fundamentally great engine had been developed by the most progressive brains of the industry.

These are the reasons for the mastership of Hispano-Suiza.

COLONEL DEEDS NOT TO BE COURT-MARTIALED

(*Concluded from last issue*)

III

Statement Regarding Transfer of Stock in Domestic Building Company

The affidavit of Judge McCann, Colonel Deeds' attorney, which was submitted to this office, shows that the Domestic Building Company was a corporation created for the development of certain real property near Dayton, Ohio, including the erection and leasing of factory buildings. The company had, at the time Col. Deeds was commissioned, about completed a large factory building for the use of the Domestic Engineering Company, which was engaged in manufacturing Delco light plants. It was contemplated that this property was to be leased to the Dayton Wright Airplane Company for the manufacture of aeroplanes. At the time when Judge McCann went to Washington at the request of Col. Deeds when the latter was commissioned, he prepared, and Col. Deeds signed and forwarded a resignation as President and Director of the Domestic Building Company. At the same time he prepared the letters to the Aircraft Production Board and to the Secretary of War heretofore discussed. In the letter to the Aircraft Production Board he stated that he had made a bona fide transfer of all his stock in the Domestic Building Company.

Col. Deeds' instructions to Judge McCann had been to promptly take all steps necessary to carry into legal effect the various transfers mentioned in the letter. On Judge McCann's return to Dayton he found that the Dayton Wright Airplane Company had determined to purchase outright the plant erected by the Domestic Building Company, instead of carrying the property by lease. Under these circumstances Judge McCann stopped action on the resignation of Colonel Deeds from that company, and advised that the transfer of his stock was not necessary; and as a matter of fact the transfer was never made.

It appears from Colonel Deeds' testimony taken by Judge Hughes, that prior to writing the letter of August 28th, Mr. Kettering had agreed to take this stock off of Colonel Deeds' hands at whatever the books showed its value to be, should it become necessary to make the transfer, though the agreement was not in writing which would not be unnatural in view of the close relations existing between these gentlemen.

Upon th evidence now before this office it is of opinion that court-martial proceedings against Col. Deeds, based upon his statement regarding his stock in the Domestic Building Company, should not be instituted, because (1) at the time the statement was made an arrangement had been entered into for the sale of this stock at its book value; (2) it took time to ascertain the book value and close the details of the transaction; (3) it was the *bona fide* intention of Col. Deeds to make the formal transfer, and he had given instructions to have this done; (4) the reason why it was not done was that through a legitimate change of plan, the occasion for the transfer was obviated, and both parties to the contemplated transfer were willing that the agreement for transfer should be cancelled; (5) the whole proceeding was conducted in good faith and under the advice of counsel.

IV

Publication Regarding Aircraft

The following is contained in the original memorandum from this office, the statements having been based solely upon the report made by Judge Hughes of his investigation of the aircraft situation:

"The report of Judge Hughes also finds that Col. Deeds authorized and sanctioned issuance for publication of a false and misleading statement by the Committee on Public Information, concerning the shipment of American-built battle planes to France. The official statement by the Committee on Public Information released for publication in the newspaper on February 21, 1918, contained the following:

" 'The first American-built battle planes are today en route to the front in France. This first shipment, though in itself not large marks the final overcoming of many difficulties met in building up this new and intricate industry.' (P. 116.)

"It is found that this statement had its origin in a conversation between Colonel Deeds and a representative of the Committe on Public Information a week or two before the completed statement was issued. A draft was first prepared and submitted to Colonel Deeds, who examined it and made some corrections. The statement contained in the paragraph above quoted was not only left unchanged, but was the subject of special inquiry by the representative of representatives of the Committee. Col. Deeds was asked what was mant by the 'fisrt shipment,' and he replied: 'They are on the water now, on the way to France.' He was then asked: 'How many?' and he answered, 'I do not know, but I do not think more than ten.' The statement, in its final form, was then presented to the Secretary of War, who permitted it to be issued upon the understanding that it had been verified by General Squier and Col. Deeds. At the time this statement was issued, February 20th, only one plane had been delivered for shipment to the American Expeditionary Forces, and while this had been shipped from the factory on February 5th, it did not leave the United States until

March 22d. No additional shipments of aeroplanes for the use of our forces abroad were made until April 3, 1918. The report states that Colonel Deeds admitted that this statement was brought to him before its publication, and that he went through it. He examined it minutely enough to correct with his own hands one of the paragraphs following that above quoted, which gave the number of men required on the ground for every plane in the air, his correction making it 46 instead of 45. Col. Deeds denied, however, that he said in response to the inquiry upon the point that the battle planes were 'on the water now, on the way to France.' That he did make this statement, it is found, was testified to directly and unequivocally by John W. McConaughy and Marlen E. Pew, representing the Committee on Public Information."

Since the matter has been re-referred to this office for examination based upon all facts known to the Department and for further report after examining the testimony taken by Judge Hughes, careful consideration has been given to the testimony on the subject. An intellignt understanding of the facts can only be obtained after a somewhat detailed statement of the evidence, which will involve a description of three exhibits filed with Judge Hughes, labeled respectively, "McConaughy Ex. 1," "McConaughy Ex. 2," and "McConaughy Ex. 3."

What was known as "McConaughy Ex. 2" was a typewritten statement consisting of three pages, the first page containing at the top two paragraphs, of which the paragraph quoted in the Hughes report was the *second*. These two paragraphs of this exhibit were pasted upon a page, immediately below which appeared two other paragraphs, the first of which had been stricken out with lead pencil, and had superimposed upon it another pasted paragraph. It will be observed that the first page of "McConaughy Ex. 2" therefore was considerably mutilated. The second page consisted of a blank page upon which was pasted a sheet of paper containing three paragraphs. The third page was typewritten without anything having been pasted upon it.

"McConaughy Ex. 3" was practically a copy of "McConaughy Ex. 2" as it appears in its present condition, this copy having been prepared in the office of Mr. J. W. McConaughy, an employee of the Committee on Public Information. It was prepared with the object of having it mimeographed for publication by the press of the country. "McConaughy Ex. 1" was a mimeographed copy of "McConaughy Ex. 3."

Although the evidence clearly establishes that Colonel Deeds never saw either the papers marked "McConaughty Ex. 1" or "McConaughy Ex. 3," yet, when he was called as a witness during the prosecution of the inquiry, he was handed "McConaughy Ex. 1" and asked if he had ever seen it before, to which he responded that he had and that he had seen it before its publication, although he had read it only in a very general way. As the fact clearly demonstrated by McConaughy's testimony is that Col. Deeds had never seen "McConaughy Ex. 1," it is necessary to consider what he actually did see in the general way he mentioned. McConaughy could not throw any light on this subject. He testified that he was not present at any interview when any paper was submitted to Col. Deeds. The only persons present at such an interview were Captain Sweetser, an officer of the Signal Corps, and Marlen E. Pew, an employee of the Committee on Public Information. Capt. Sweetser testified that he had written up "McConaughy Ex. 2" sometime before, with the exception of the paragraph relating to the Liberty Motor (which was the third paragraph on "McConaughy x.2," being a paragraph which had been pasted over the original third paragraph thereof); that "McConaughy Ex. 2" had been written up after a chance talk with Col. Deeds during the course of which the latter had stated that we were "over the bump" and "the planes had actually begun going or something of that sort," something which Sweetser interpreted to mean that the planes were actually *en route*, although Sweetser would not swear that Col. Deeds told him that the battle planes were actually *en route* to France; that he had subsequently presented this statement to Colonel Deeds and that Deeds had told him that he had decided not to give it out at that time; that later on Sweetser went over to the Committee on Public Information and saw McConaughy and Pew and suggested to them that the story should be written up stating that the first battle planes were going across; that he returned with Pew to the Department and wrote up a paragraph to the effect that the planes as equipped with the first Liberty motors were being shipped; that he and Pew then went in to see Col. Deeds and submitted 'the story" to him and that Col. Deeds sat on the desk and read it through; but that the statement submitted to Deeds was not "McConaughy Ex. 2" at all, but that the paper submitted to him contained a statement that the Liberty motor had 450 horse power, and that Col. Deeds instructed Sweetser not to make that feature public. Capt. Sweetser said, however, that the paper that was submitted to Deeds did contain a statement that the first American-built planes "are today *en route* to the front in France." The particular paper which Sweetser said Col. Deeds saw was not identified nor produced.

Mr. Pew testified definitely that the paper submitted to Col. Deeds on this occasion was "McConaughy Ex. 2" *without the first two paragraphs* on page 1. This statement is important because it is the *second* paragraph on page 1 which is the subject of the criticism against Col. Deeds. They both agree, therefore, that Col. Deeds never saw the second paragraph of "McConaughy Ex. 2," unless the testimony of Pew is correct to the effect that after the first interview with Col. Deeds at which he and Captain Sweetser were present, they rewrote paragraphs 1 and 2 of page 1 of "McConaughy Ex. 2" and then took it back to Col. Deeds, who read it over carefully and changed the figures "47" to "46" as they appear in the 4th paragraph of the first page of that exhibit, and at the same time Capt. Sweetser made several pencil changes on the first page of that exhibit in Col. Deeds' presence. The fact should be borne in mind that paragraphs 1 and 2 of page 1 of that exhibit are pasted on to the page containing paragraphs 3 and 4.

In this connection it is noteworthy that Captain Sweetser testified that these paragraphs land 2 on page 1 had been written long *before* the interview with Col. Deeds about which he testified, and not *afterwards*, and that the pencil changes made by him were made *before* the paper was submitted and not *afterwards*, Capt. Sweetser made no mention of a second interview with Col. Deeds, and says that at the conclusion of the interview about which he testified, he and Pew separated and that Pew went back to his office.

It is also important to observe that, whereas Pew testified that Col. Deeds stated at the second interview that the planes referrrd to in the second paragraph of "McConaughy Ex. 2" were on the water, Capt. Sweetser testified that Col. Deeds said nothing specific about that but he (Sweetser) gathered that impression from the fact that Col. Deeds had stated that the planes had been shipped, "because the question of shipment from Dayton to Hoboken had not come into his mind." McConaughy testified that before Capt. Sweetser and Pew had the conversation referred to, he himself had a conversation with Col. Deeds in which the latter had told him that the planes were on the water, and that he (McConaughy) repeated this statement to Pew and suggested that Pew interview Col. Deeds and write an article on the subject.

Th evidence plainly establishes that McConaughy was anxious to get a news item about the planes which would tend to allay the public dissatisfaction with the lack of progress apparently being made. But no mention was made in the article which was written for publication of that feature which if true would have been the most important piece of news of all, to wit: that the planes were on the ocean. The omission of this item in "McConaughy Ex. 1," "McConaughy Ex. 2" and "McConaughy Ex. 3" is a pertinent fact to be considered in connection with the testimony of McConaughy and Pew, as contrasted with the testimony of Captain Sweetser, above recited, and that of Col. Deeds to the effect that he did not tell either McConaughy or Pew that the planes were on the ocean. Col. Deeds also denied having mntioned any particular number of planes in referring to those which were being shipped, although McConaughy and Pew testified that he mentioned the number 10 or 12 in this connection. That number was not referred to in the report as written up.

It may well be doubted whether Col. Deeds ever made any statement as to any particular number of planes or that any of them were actually on the water. It is possible that Pew, when he gave his testimony before Judge Hughes, had in mind what he had been told by McConaughy as coming from Col. Deeds on this subject.

The very unsatisfactory testimony in the case also leaves in the mind of the careful reader a very considerable degree of doubt whether Col. Deeds ever saw the second of paragraph of "McConaughy Ex. 2" which contained the language criticized by Judge Hughes in his report.

But if he did see it, and if he authorized it to be submitted to the Secretary of War for publication as claimed, it by no means follows that it was not believed by him to be true. McConaughy fixes the date of the interview between Captain Swcetser, Pew and Col. Deeds, as somewhere between the 10th and 14th of February. Pew says it was the 14th or 15th of February. Col. Deeds says that his information at the time of that interview was that four planes were then on the cars on their way to France; and that is as far as the information set forth in the second paragraph of the "McConaughy Ex. 2," "McConaughy Ex. 1" and "McConaughy Ex. 3" extends. There is nothing contained in the testimony taken at the inquiry or in any facts known to this office, to indicate that Colonel Deeds had any different information. The testimony shows that at least one plane had been shipped from Dayton on February 5th intended for foreign service, and that it reached Hoboken in two parts on February 26th and 28th. The telegram asking that it be recalled was not dated until February 14th. It must be remembered that while the statement was not published until February 21st, the conference with Col. Deeds had been held at least a week before its publication and perhaps more. Whatever statements Col. Deeds made were obviously made based upon his understanding of the condition of things as of that date, and could not have related to a changed situation which developed during the week or ten days succeeding.

In the affidavit submitted by Colonel Deeds which is forwarded herewith he says:

> "The facts are that the Dayton Wright Airplane Company, up to February 16, 1918, shipped four battle planes. Col. Deeds was informed and believed that those machines had been shipped from the factory to go to France. They are the machines referred to in the above statement. In his explanation before Judge Hughes, October 3, 1918, he made the following explanation:
>
> "'I have only the explanation of the four planes about which I have just spoken. I had very definitely in my mind that there were a total of four planes that had been shipped, but I learned later that three of these had been diverted to Gerstner Field, but I did not know that at the time I looked over this. I made no statement that they were on the water, but that they were shipped.'"

It is recommended that no court-martial proceedings be instituted against Col. Deeds based upon this publication because: (1) it is doubtful whether he ever saw the paragraph which has been adversely criticized; and (2) the statements contained in it are in accord with what Col. Deeds apparently believed and had reasonable cause to believe to be the facts.

V

Testimony Before Senate Military Committee

It was stated further in the report of Judge Hughes that when Colonel Deeds was examined as a witness before the Committee on Military Affairs in the Senate on April 2, 1918, he was asked this question and gave this answer:

"Senator Wadsworth: Did you see or did you know whether any other responsible officers in your aviation section of the Signal Corps saw the statement given out by Secretary Baker on February 21, before it was published?

"Colonel Deeds: No, sir, I did not see it. I do not know of anybody seeing it." (P. 117.)

The report states that Colonel Deeds admitted giving this testimony, and that he testified that he did not then recall the paper in question. Judge Hughes, in his report, failed to set forth the remainder of Colonel Deeds' testimony as given by him before the Senate Committee.

Further consideration has been given the matter in the light of all the testimony of Colonel Deeds on the occasion in question.

The question that was asked Colonel Deeds by Senators Wadsworth referred to a statement given out by Secretary Baker on February 21, without particularly identifying the statement. Inasmuch as Colonel Deeds (as the record of the Hughes inquiry shows) had never seen Secretary Baker in regard to any statement which was to be given out on February 21, it is very natural that he should have replied that he did not see the statement. Up to that moment it does not appear that the particular statement in the mind of Senator Wadsworth had been called to Colonel Deeds' attention. Further questioning, however, elicited from Colonel Deeds information which showed that his negative answer to Senator Wadsworth's question had been given in perfectly good faith. When immediately following the question referred to, he was asked by Senator Wadsworth whether he or any other officer of the Department consulted with Secretary Baker or with Mr. Creel before the Secretary authorized the statement, Colonel Deeds answered:

"No, sir, I did not see Mr. Creel. I did not see Mr. Creel until a few weeks ago. I had not met Mr. Creel up to that time. I knew that some one from the Bureau of Information came into the Chief Signal Officers' office and asked some questions, and the statement was made that we were behind production, but that according to the original arrangement, our planes were to be supplied up until July 1 from abroad, by France and Italy, and our planes were to follow, that while we were behind our schedule, at the same time we saw no reason why Pershing's forces would not be equipped because of this delay.

"Senator Wadsworth: You were present and overheard that conversation.

"Colonel Deeds: I remember a conversation just about like that that I had myself with someone from the Bureau of Public Information who came into the General's office along about that time.

"Senators Wadsworth: It was not Mr. Creel?

"Colonel Deeds: No, sir.

"Senator Wadsworth: Was it Mr. Rubel?

"Colonel Deeds: No, sir.

"Senator Wadsworth: Was it Mr. Strunsky?

"Colonel Deeds: I do not know him.

"Senator Wadsworth: You cannot remember who it was?

"Colonel Deeds: I do not know.

"Senator Wadsworth: Was there anything to justify the statement that we were five months ahead of the program.

"Colonel Deeds: No, sir, not in what I said.

"Senator Wadsworth: Did any officer say anything to justify the statement?

"Colonel Deeds: No, sir."

None of the testimony quoted above appears in the Hughes report. It indicates that Coionel Deeds informed Senator Wadsworth at that hearing regarding the conversation with Mr. Pew the, details of which appear to have escaped his mind at the time. If, as a matter of fact, Colonel Deeds had not seen the second paragraph of "McConaughy Ex. 2" before publication, and did not state that the planes were then on the water, it is quite conceivable that without intending to make any false statement, he may have given the testimony he did in perfectly good faith, more especially as the statement itself, which was exhibited to him at the Sweetser-Pew interview, or was claimed to have been exhibited to him in typewritten form at that time, was not before him at the Senate investigation, as it subsequently was during the Hughes inquiry.

The following explanation by Colonel Deeds appears in his affidavit hereinabove referred to:

"As to Colonel Deeds testimony before the Committee on Military Affairs of the Senate on April 2, 1918, Colonel Deeds admitted giving that testimony, and explained at the time of his examination by Judge Hughes, and still asserts, that at the time he testified before the Senate Committee, he did not recall having seen the statement before the newspaper publication. The submission of the statement to him was only an incident in the rush of business, and at the time of the testimony before the Senate Committee, he had in mind publications in the newspapers, which had considerably elaborated upon the facts contained in the original decument. Between that time and the giving of his testimony in the Aircraft Inquiry, his recollection was refreshed by an investigation he made upon hearing that a witness who preceded him had been examined as to what extent Deeds was responsible for the statement. His testimony on each occasion, though there is a conflict, was entirely truthful, according to the recollection he had at the respective times. With the information that Colonel Deeds had at the time the statement was made, and which he believed to be true, there was nothing improper in the purpose or purport of the statement itself.

"The information Deeds had was not inconsistent with Talbott's telegram of February 14, 1918 (P. 117). The information was that the shipments had been made, one on February 11 and three on February 15. So the telegraphic reference on February 14 to one plane shipped was according to information. Talbott's reference to the first hundred remaining in this country was not official, nor did that happen."

In the light of the information now before this office, it is recommended that no proceedings before court-martial be instituted because of the statement made by Colonel Deeds before the Senate Committee, because the evidence does not show that he made a wilful false statement before that committee.

VI.

Packard Company Vouchers

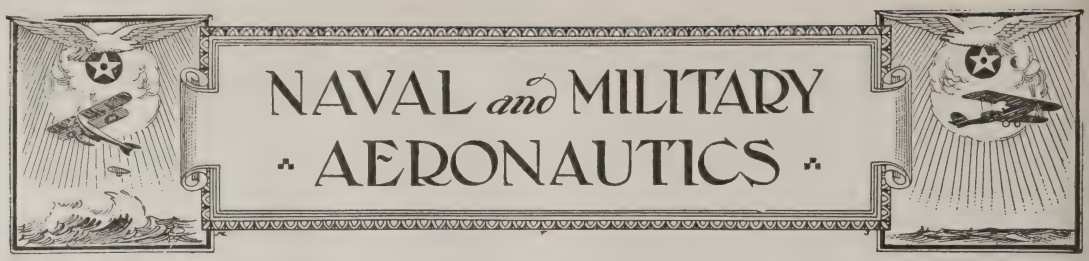
The last transaction with which Colonel Deeds was connected, discussed in the memorandum submitted by this office on November 11, 1918, is the irregularity charged against him in approving two out of four vouchers in favor of the Packard Motor Car Company, these four vouchers aggregating $249,159.10. These acts of Colonel Deeds were not made the basis of any recommendation by Judge Hughes in his report, but were noticed by this office which made the statement in its previous memorandum that from the facts stated in the Hughes report it was impossible to say whether Colonel Deeds' act in this connection constituted a violation of any of the Army Regulations relating to money vouchers or such other breach of his official duty as to furnish the basis for charges against him.

Consideration to this subject has again been given in the light of the evidence disclosed upon the record of testimony taken before Judge Hughes and additional facts brought to the attention of this office.

One of the criticisms directed by Judge Hughes against this transaction is that there was no contract in writing with the Packard Motor Company covering this work. It is to be noted that the work was originally ordered at a time when Colonel Deeds was not in the Army; and the first voucher for payment on account which was approved by him was approved while he was acting as a civilian employee of the Government, for a yearly compensation of one dollar. The omission of a formal written contract, if Mr. Deeds was to blame for this at all, which is not clear from the record, is not attributable to him as an army officer. When he was called upon to approve the vouchers for payment the work was already in progress. With respect to Judge Hughes' criticism that no price had been fixed in advance, attention is invited to the following statements taken from a memorandum submitted to this office by Major E. A. Coleman, disbursing officer of the Bureau of Aircraft Production. The statements contained in that memorandum are supported by evidence taken before Judge Hughes:

"It is my understanding that the Aircraft Production Board secured the services of the Packard Motor Car Company to conduct certain experimental work in connection with the development of an airplane engine and to produce certain standardized engines, and that the Packard Company could not state in advance the cost of such experimental work, and that it was orally understood that the Signal Corps would reimburse the Packard Company their actual cost, plus a reasonable amount to cover administrative expenses, profits, etc. Before the delivery of the engines aforesaid covered by voucher No. 7228, it was agreed that certain definite unit prices would be paid therefor.

"These prices were arrived at, as I understand it, from estimates furnished by the Packard Company. In any event, the amount to be paid for such engines had been agreed upon by the Packard Company and by the representative of the Government, prior to the certification of the voucher.



"It is also my understanding that services of the Packard Motor Car Company were secured because it was considered that they were better equipped to handle this character of experimental work than other firms available for the purpose, under an emergency and stress of urgent public necessity that did not permit of delay, and that the methods employed to secure the services of this firm are authorized under orders dated April 12, 1917, signed by the Secretary of War. If I correctly understand the facts in this matter, the certificate executed by E. A. Deeds, Col. Signal Corps, on voucher No. 7228 of December, 1917, Captain H. Elliott's accounts, is regular and executed in conformity with the requirements of the regulations of the Signal Corps, literally true in all its essentials and justified by the facts."

The Aircraft Production Board set aside an appropriation of $250,000.00 to cover the cost of the work. As the work progressed the Packard Company required money on account. Estimates were made of the amounts earned from time to time and four separate vouchers were made to cover all the payments to the Packard Company on this account. Only the third of this series was approved by Colonel Deeds while an officer of the army. That was dated December 6th, and was for $60,000.00. Up to that time two vouchers for $104,500 and $73,194.72 respectively, had been paid on account. The Packard Company had a complete record of all the transactions, and this record, while it does not appear to have been filed with the War Department, was gone over by Lieut. Colonel Vincent and used as the basis for payment. The Packard Company complained that it had lost money on the work.

Captain Oscar R. Ewing, of the contract section of the Bureau of Aircraft Production, testified that it was the custom of the service, on experimental work, sometimes to pay vouchers on a mere allotment of funds and an order, either verbal or in writing, against that allotment; but that these cases usually involved only small amounts.

Major General George O. Squier, Chief Signal Officer, testified that

General Lee Returns Home

Brigadier General Charles Frederick Lee, R. A. F., Chief of the British Aviation Mission, sails for England on the "Adriatic," February 8th. Following his service with the British Expeditionary Force in 1914, 1915 and 1916, General Lee returned to England to command the Training Brigade, R. F. C. He joined the British Mission to the United States on November 30, 1917, as officer commanding the Aviation Mission. His home is Grove Hall, Knottingley, Yorks, England.

Italian Service Ribbons to American Airmen

Forty-eight officers of the Air Service and one officer of the Medical Reserve Corps detailed to the Air Service have been authorized by the Italian Minister of War to wear the Italian Service Ribbon, instituted by Royal Decree 641 May 21, 1918, according to a communication from the Chief of the Air Service, A. E. F. The officers named have returned to the United States and so their official certificates from the Italian Government have been sent to the Division of Military Aeronautics for distribution.

The names and home addresses of the officers follow: Captains: Edmund A. Kruss, San Diego, Calif.; Oliver B. Kiel, (Medical Reserve Corps) no address. First Lieutenants: Lawrence N. Campbell, Owatorma, Minn.; Wallace H. Carpenter, Duluth, Minn.; Robert P. Clarke, Jr., Sewickley, Pa.; Lenan O. Conley, Penn Yan, N. Y.; Frederick G. Dodge, Genesee, N. Y.; Ross R. Dunn, Noblesville, Indiana; Horace Drever, Philadelphia, Pa.; Thomas F. Fielder, Spartansburg, S. C.; Bicknell Hall, Jr., Taunton, Mass.; George S. McKey, (MacKey) Chicago, Ill.; Edward B. Mayer, Iowa City, Iowa; Edward M. Malley, Greensburg, Pa.; Willard S. McKay, Plainfield, N. J.; Edward M. Ogden, Rochester, N. Y.; Charles P. Penney, Buffalo, N. Y.; David S. Pruitt, Bethany Beach, Del.; Earl D. Ranck, Overbrook, Pa.; Samuel S. Robinson, no address; Lawrence G. Sherman, Brattleboro, Vt.; Horace L. Stevenson, 157 U St., Washington, D. C.; Oliver H. Stout, Indianapolis, Ind.; Verlie Van Zele, Genesse, Ill.; Paul J. Wedel, Jersey City, N. J.; George O. Wright, Fort Valley, Ga.; Linus V. Windnagle, Portland, Oregon; William P. Young, Clearfield, Pa.; Clarence M. Young, Des Moines, Iowa; Walter T. Mayer (Meyer), Columbus, Ohio; Walter M. Boadway, Princeton, N. J.; Lester B. Cowgill, no address; Hugh D. Stier (Stark), Pittsburgh, Pa.; George N. Nyland (Hyland), Philadelphia, Pa.; John N. Devoe, no address; Frank C. Cox, no address. Second Lieutenants: Paul H. Cresswell, Cedarville, Ohio; William J. Flynn, Detroit, Mich.; Hugh J. Gaffney, Jersey City, N. J.; Richard Goodman, Philadelphia, Pa.; William M. Malcolm, Hartford, Conn.; Thomas J. Mitchie, no address; Raymond W. T. Ricker, New Durham, N. H.; Herman Schmidt, 2813 N. Cap., Washington, D. C.; Horace S. Stevens, no address; John A. Posy, no address; Lawrence D. Messner, Wilkinsburg, no address; Lawrence J. Joseph, Galveston, Texas; John W. Canon, no address.

Official Publications for Flight Surgeons

Three interesting and instructive publications on the medical side of flying prepared by members of the Air Service, Medical, are now in press.

The first of these pamphlets will appear under the title "The Air Service, Medical Manual." It will comprise four chapters concerning the conservation of human material, as well as the conservation of machines as developed in practice in the U. S. Air Service. The development of the "Trouble-shooter" of the flier as compared to the trouble-shooter of engines and machines was developed in the person of the "flight surgeon."

The second publication is more general in character and also more extensive. It is issued under the title, "Air Service, Medical," and comprises 500 pages of text with 275 full-page illustrations. It is a story on the general standpoint of the medical aspect of aviation from Langley's experiments to the Aeronautical achievements of the present day. It is the doctor who makes flying safer, through selection, classification and maintenance of the fliers. Under the last sub-division are explained the duties of the physical director and nutrition officer.

The third publication is more technical and deals with the internal working of the medical research laboratory established for the Air Service at Mineola, L. I.

A group of aeronautic enthusiasts at Wilbur Wright Field. Second from the right, standing, is Col. J. G. Vincent, and kneeling at the right, Walter E. Lees, pioneer aviator

FOREIGN NEWS

Polish Air Service

In its stand against the Bolsheviki Poland is handicapped by lack of adequate air service, there being only fourteen old training planes available. Efforts are being made to purchase planes in Vienna and it is reported that the United States Government has dispatched several planes for the use of the Polish Army.

British Lift Experiment Ban

The Ministry of Munitions has suspended the regulation prohibiting the experimental manufacture without license of any aeroplane, seaplane, or any aero engine or part thereof. This order prohibited even the making of detail drawings. Lumber may again be bought and sold without license.

The priority for many uncompleted war contracts has been lifted, permitting firms to accept orders for peace business and give them priority over war contracts.

The whole industry will welcome this return to peace conditions and development of commercial aircraft can proceed unhindered by Government regulation. The commendable foresight of the Ministry of Munitions in restoring peace conditions as rapidly as possible may tend to influence American policy.

French Distribute Food By Aeroplane

In certain districts in Northern France the Germans, in their retreat, so thoroughly destroyed the bridges and railways as to render the delivery of food supply highly difficult. The French Government has decided to use aeroplanes for the purpose.

Germany Plans to Dominate Swedish Aircraft Market

German aircraft companies, immediately following the signing of the armistice, sent several of the latest type of twin-motored planes to Stockholm, with a view to capturing the Swedish market. Trial flights are frequently made and the machines offered at tempting prices.

It is suggested that Allied and American manufacturers make an effort to secure a part of this prospective trade, as the opportunities are excellent. Sheltered by numerous islands and inlets, there should be a lively demand for seaplanes.

Air Transportation in China

Owing to the difficulty which would be encountered in the transportation of materials for the erection of three commercial wireless stations in remote parts of China, the Marconi Company has arranged with Mr. Handley Page for their delivery by aeroplanes. No part of the machinery to be used will weigh more than 300 pounds. By ordinary methods of transportation it would take two to three months to convey the radio instruments across China as against the same number of days by aircraft.

British Seek Air Route Concession in Brazil

Rio de Janeiro, January 21.—A British aeronautic concern has requested a concession to establish an air route between Rio de Janeiro and Pernambuco. It is intended to extend the system to Buenos Ayres.

Royal Air Force Lose Polo Championship

By sustaining a 13½ to 8 defeat on January 22nd at the hands of the White Owls the Royal Air Force lost its chance of winning the Victory Cup for the Canadian polo championship.

British Companies to Insure Aviators

According to a statement of an important official of a large British insurance company, it is quite probable that insurance companies will write life insurance for aviators. At the present time insurance is not unobtainable, but companies will not pay on policies or return premiums paid if the flying accident occurs within three years of issuance of policy.

A French Nieuport Scout

Canada Plans Aerial Development

Coincident with the announcement of the British civil committee of the Air Board proposing interimperial aerial scheme, the Canadian civil authorities have also taken up the matter along national lines. With this object in view representatives from the various centres of the Dominion have already consulted the Federal Cabinet, with the result that earnest consideration will be given to the question of future aviation in Canada. One of the suggestions discussed at the Ottawa conference was the establishment of a national aeronautical advisory committee for the purpose of going into the whole matter exhaustively. E. W. Beatty, president of the Canadian Pacific Railway, was named president of the committee. Mr. Beatty, who is only 41 years of age, recently succeeded Baron Shaughnessy as president of the C. P. R. Mr. Beatty is a King's Counsel and reached his present high position after seventeen years of hard work with the railway.

International Laws of the Air

An Inter-Allied Aeronautical Conference will be held at Paris in the spring of 1919 for the purpose of establishing International Law for aircraft. It is probable that pilots will be required to carry passports, and when crossing from one country to another will be obliged to stop at designated fields for identification and customs inspection.

Arrivals at the International Aerodromes will be entitled to the latest meteorological information and directions regarding the cross-country air routes.

Certain areas will be banned for the aerial traveller for military reasons.

Lord Weir On Commercial Aeronautics

Manchester.—In discussing the future of commercial aeronautics, Lord Weir, Secretary of State for the Royal Air Force, stated that its success would be largely dependent upon the development of the science of aerial navigation; the careful and thorough training of aerial navigators; the perfection of navigating instruments; the organization of an extensive meteorological service; the adoption of standardized night and day marking of landing fields, and the employment of radio telegraphy and telephony for communications. These factors will contribute to the safety and reliability of commercial navigation and their development has not kept pace with that of design and construction of commercial aeroplanes.

Lord Weir is opposed to government monopoly of aerial transport. He urged the permanent acquisition of all military aviation fields in order that they may be made available for commercial travel.

Air Route to Far East

Melbourne, Australia, January 22.—The Australian Government, it is announced, has sanctioned the formation of a company to survey an aerial route between Australia and the Far East.

British Air Force Had 294,000 Officers and Men

London, Jan. 23.—Great Britain was pre-eminent in aviation at the close of the war, when her air force was the largest in the world, according to a report made public recently. It fought on more fronts than the air service of any other nation in the war.

In August, 1914, the British naval and military air services together mustered only 285 officers and 1,853 men of other ranks. In November, 1918, there were 30,000 officers and 264,000 men. At the outbreak of the war Great Britain had 166 aeroplanes, forty-five seaplanes, and seven airships, while at the close of hostilities she had 21,000 aeroplanes, 1,300 seaplanes, and 103 airships. Besides this there were 25,000 aeroplanes and seaplanes being built and 55,000 aeroplane engines under contract.

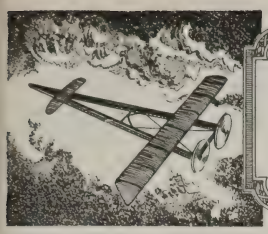
The Women's Royal Air Force, which was not in existence in 1914, numbered at the close of the hostilities 23,000.

New Italian Speed Record

Rome, Jan. 24.—A new Italian biplane, the Marchetti Vickers Terni, piloted by Sergeant Elia Lint, has attained under official trials an average certified speed of 160 miles an hour.

The trials were conducted at a height of nearly a hundred feet from the ground, so the controls were flattened in flight, and the flights were made both with and against the wind.

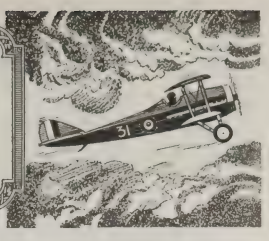
The motor was of the 200 horsepower Spa type. The average speed attained exceeds by sixteen miles the previous record under similar conditions.



Italian "White Eagle" for Ocean Flight

London.—The correspondent of *The Daily Telegraph* at Milan reports that Signor Caproni has nearly finished the gigantic machine in which it is intended to fly from Italy to America. The machine is a huge triplane with engines of 3,000 horsepower and ample accommodation for a certain number of passengers, for whom cabins and sleeping berths will be available.

The Caproni transatlantic flier is to be named the White Eagle, in allusion to a curious prophecy printed here in 1916 and attributed to an English friar of the seventeen century. The prophecy announced that there would be a great world war in the twentieth century, which would be started by the evil genius of an Emperor in Luther's country in league with another Emperor, both of whom had black eagles on their coats of arms, but that civilization would eventually crush the barbarians, whose empires would be divided up into twenty-two States.



The white eagle in phophecy is interpreted to be the American eagle. Verses on the subject, written by a local poet, W. Lewis, and set to music, were presented, with a beautiful design drawn by two Italian artists in gold and colors, to President Wilson when he was in Milan. It was on seeing this design and poem that Caproni decided on the name for his machine.

It is proposed that the aviators take the same route as Columbus did, flying from Italy to Cadiz and the Azores and thence to the American coast and landing near Washington.

ELEMENTARY AERONAUTICS
and
MODEL NOTES

By John F. McMahon

Model Aeroplane Building as a Step to Aeronautical Engineering

WE will now proceed to check up the possible performances of our machine.

Our first problem is to correctly ascertain the wing resistance at the different speeds. Now the reader will notice that the wing resistance is high at low speeds due to the larger angle of incidence necessary to fly at low speeds. (The reader will remember that to fly at certain speeds we can alter the area, speed, or angle of the planes.) We cannot change the area in flight and we wish to fly at a low speed so we simply alter the incidence by pulling back the control stick and lowering the tail until the correct angle for minimum speed is reached. For the R. A. F. 6 section this occurs at 16 degrees when the lift coefficient is highest.

By consulting the accompanying chart we will see that the resistance is also high due to the greater area presented to the wind. When checking up the performance of a machine the parasite or non-lifting resistance is figured separate to the wing resistance and you will notice that at low speeds the parasite resistance is small and gradually increases with the speed, while the wing resistance is high at low speeds owing to the large angle of incidence and as the speed increases the angle becomes less and of course the resistance comes down and then it starts to climb again as the aeroplane begins to get into high speed.

The resistance coefficient at 16 derees is .000446 then our wings will have a resistance of

coefficient surface M.P.H.

$.000446 \times 206 \times 37^2 = 126$ lbs. approx.

But as the speed increases the angle grows less and we find that at the maximum speed of 60 M.P.H. we will use an angle at which the wings are set on the aeroplane which is 4½ degrees.

The resistance coefficient at 4½ degrees is about .000102 then at 60 M.P.H. our wings will have a resistance of only

coefficient surface M.P.H.

$.000102 \times 206 \times 60^2 = 75$ lbs. approx.

The reader will see that the resistance of the wing is much higher at the lower speed than at the higher.

Now the coefficient of resistance of a radiator is .00173 and we have approximately 2 sq. ft.

$.00173 \times 2 \times 37^2 = 4.7$ lbs.
$.00173 \times 2 \times 60^2 = 12.46$ lbs.

Now the skin friction of a body is regarded as .03 per sq. ft. at 60 M.P.H. and .0114 at 37 M.P.H. We have a surface on the body of approximately 90 sq. ft., then the skin friction at 37 M.P.H. will be $.0114 \times 90 = 1.03$ lbs. and at 60 M.P.H. it is $.03 \times 90 = 2.7$ lbs. this, of course, is neglecting the hole in the cockpit and the aviator's head. It would be fair to add 2 lbs. at 37 M.P.H. and 5 lbs. at 60 M.P.H. for this which would bring the body resistance up to

	37 M.P.H.	60 M.P.H.
Radiator	4.7	12.46
Skin Friction	1.03	2.7
Resistance of Cockpit and head	2.00	5.00
Total	7.73 lbs.	20.16 lbs.

This resistance due to the slip stream of the propeller is increased 25% which makes these resistances 9.66 lbs. and 25.2 lbs.

We have 42 feet of struts and the resistance 12.8 lbs. per 100 feet of strut at 60 M.P.H. The struts then have a resistance of $\frac{42 \times 128}{100} = 5.38$ lbs. at 60 M.P.H. and 2.05 lbs. at 37 M.P.H.

Wheels have a resistance of about 1½ lbs. each at 60 M.P.H. that is if they are covered with cloth or metal to make a streamline shape. Two wheels would be 3 lbs.

The landing chassis, struts, axle, etc., have a resistance of 5 lbs. at 60 M.P.H.

The rudder, tail, etc., have a resistance of 3 lbs. at 60 M.P.H. This is increased 25% owing to the slip stream of the propeller which increases this to 3.75 lbs. at 60 M.P.H.

The wires, control arms, fittings, etc., add another 3 lbs.

Our parasite resistance is then

Body	25.2 lbs.
Struts	5.38
Wheels	3.
Landing Chassis	5.
Rudder, etc.	3.75
Incidentals	3.
Total	45.33 lbs. for the body at 60 M.P.H.

At 37 M.P.H. this resistance would be

$37^2 : \times :: 60^2 : 45.33$ lb. = 13 lbs. approx.

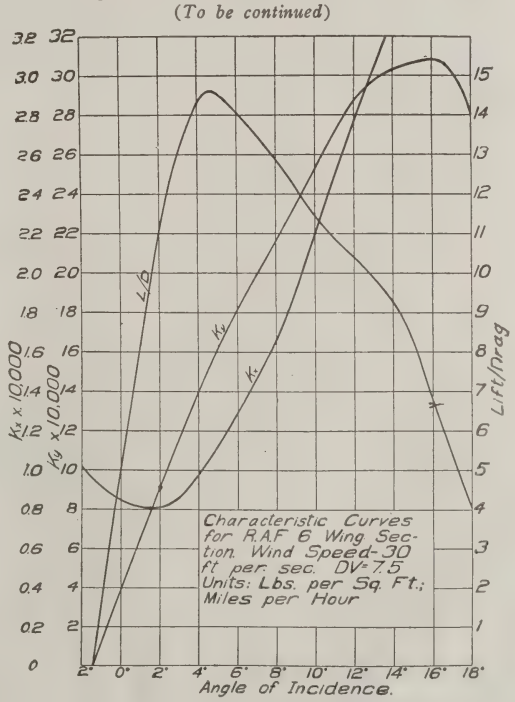
Our total resistance is then

Wings	37 M.P.H.	126 lbs.
Parasite	37 M.P.H.	13 lbs.
		139 lbs.

Horsepower required is

$\frac{139 \times 37}{375} = 13.7$ Horse Power required

Wings	60 M.P.H.	75 lbs.
Parasite	60 M.P.H.	45.33 lbs.
		120.33 lbs.



Horse Power required

$\frac{120\text{-}1/3 \times 60}{375} = 19¼$ horse power required approx.

Of course this is the actual horse power. The propeller slips 25% so we must develop 25% more horse power to give the horse power required at the propeller. This will increase our figures to 17.1 H.P. and 24.06 H.P.

A re-designed Ford motor will develop from 30 to 35 horse power so the reader will readily see that we will have a reserve horse power of from 5 to 10 for climbing.

(To be continued)

Characteristic curves for R.A.F. 6 wing section

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Says Wifey to Hubby

Harry, how I used to kid you
On our fleeting honeymoon;
When I asked you, sweetheart, did you
Have another girl to spoon.

How my habit was to tease you,
Saying "when away from home
Will some other woman squeeze you,
And will yours o'er strange lips roam?"

How I tossed my foolish banter,
Saying that I'd trust you,
Boy, forget it, please don't canter,
O'er green fields and pastures new.

Husband, dear, I have but just you,
Even if I did, in fun,
Say abroad I would not trust you
If you met a pretty one.

Now I lie awake and wonder
What you're doing over there,
Hoping, dear, that you won't blunder
From the Straight Path is my prayer.

Harry, dear, I worry daily
While you're there among the French,
Wondering if you're playing gaily
With some charming brunette wench.

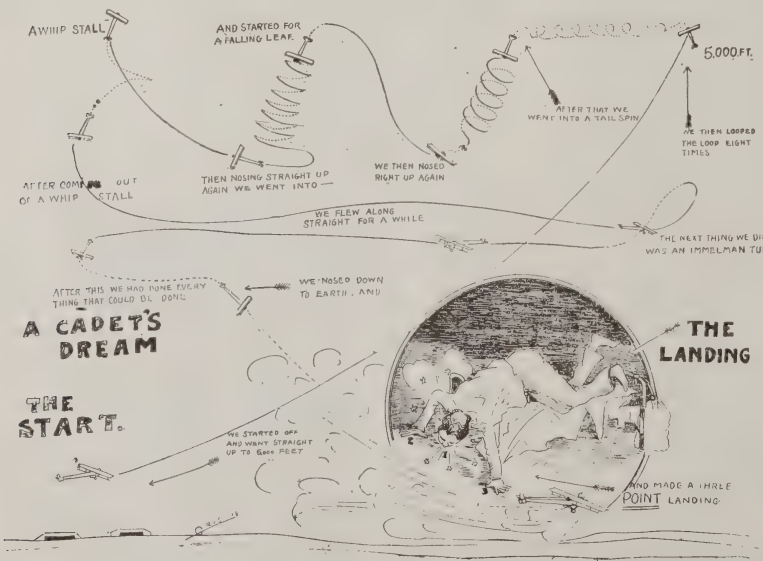
Lonesome! Sweetheart, how I miss you,
But, with patience, wait I must
For the day when I can kiss you,
Seems as though my heart would bust.

Says Hubby to Wifey

Dearest, all your prayers and wishes
I have pasted in my hat;
I'll not taste forbidden dishes,
And we'll let it go at that.

But, dear, whilst you're moralizing
On my conduct over here,
Save your brown eyes tantalizing,
Glances for your husband dear.

All my days are full and busy,
While my sweetheart sadly waits;
Sometimes, dear, my brain grows dizzy,
Wond'ring if you're making dates.



And while you're praying and pleading
For my welfare over here,
Don't let anyone be leading
You from the straight and narrow, dear

Satan always finds employment
For small hands with nought to do;
If you brood o'er my enjoyment
He may find a job for you.

You have asked me not to frolic
In green fields and pastures new;
To abstain from sports bucolic,
Likewise, love, is good for you.

And dear heart, until I meet you,
When I step down from the ship.
And with loving kiss I greet you,
Look out, dear, YOUR foot don't slip.

—Bard of Beaumont.

—*From The Fly Leaf.*

A Marine's Ride

(From the "Globe and Anchor," Galveston.)

THE OTHER DAY
I WENT UP
TO ELLINGTON FIELD
TO GIVE THE PLACE THE O. O.
AND THEY WERE AWFULLY POLITE
AND ASKED ME
IF I WANTED TO GO UP
AND I TOLD THEM I DID
SO THEY GAVE ME
ONE OF THESE
CUTE LITTLE COATS
THAT ALL THE HEROES
ON THE MAGAZINE COVERS
WEAR
AND ONE OF THESE
HELMETS
TO KEEP MY HAIR
AND EARS
FROM BLOWING OFF
AND SOME GOGGLES
AND THEY STRAPPED ME IN
WITH A SIX-INCH STRAP
AND I WONDERED
AT THE TIME
WHY IT WAS SO WIDE
AND LATER
I FOUND OUT.
WELL
THE PILOT
WHO WAS HELPING ME
TO NEED MY INSURANCE
WAS LIEUTENANT EDDIE PACK
AND BEFORE WE STARTED
THEY TOLD HIM
TO GO EASY
AND SO DID I
AND HE SAID HE WOULD.
AND WE STARTED
AND THE NEXT THING
I KNEW
THE GROUND WAS FAR AWAY
THAT IT WAS
A NEGLIGIBLE QUANTITY
AND PRETTY SOON
I NOTICED A LITTLE DIAL
IN FRONT OF ME
AND ON IT
IT SAID
"8 THOUSANDS OF FEET."
BUT THAT
WAS SUPERFLUOUS
I KNEW IT.
AND OF A SUDDEN
WE WERE HEADED
FOR THE GROUND
AT A COUPLE OF MILLION
MILES PER HOUR
AND THEN WE WERE
HEADED FOR HEAVEN
AT THE SAME RATE
AND WHEN I LOOKED UP
TO SEE IF WE HAD HIT
THE SKY YET
INSTEAD OF THE SKY
I SAW THE GROUND
AND WHEN I LOOKED DOWN
I SAW THE SKY
AND IT WAS THEN
THAT I OFFERED UP
A SILENT PRAYER
FOR THE STRAP
ABOUT MY MIDDLE,
AND ABOUT THAT TIME
WE PASSED A CROW
AND HE HAD
AN ENVIOUS LOOK
IN HIS EYE
BECAUSE EVEN HE
COULDN'T FLY
WITH HIS FEET
POINTED HEAVENWARD
AND ALL I CAN SAY
IS
IF LIEUTENANT PACK THINKS
WHAT HE DID
WAS "GOING EASY"
I WANT TO BE
ANCHORED TO THE GROUND
WHEN HE
EXERTS HIMSELF.
FINIS.

The de Havilland 4 with the Liberty engine has been one of the successful associations with America's air program. For reconnaissance and bombing, the British have used the de Havilland 4 with a 300 H. P. Rolls-Royce engine, and the adoption of the Liberty 12 has given the United States superior results in both performances and production.

Valspar *vs.* Vibration—Valspar Wins!

When an airplane equipped with a Liberty motor goes whiz-z-z-z-ing through the sky at 130 to 140 miles an hour, with its machine guns kicking at the rate of 290 a minute—

Talk about *vibration!*

Just a steady Z-n-n-n-n-n of vibrating wires and wings!

Any varnish that is elastic enough to withstand such vibration is *some varnish!*

The experience of the last year of the war proved conclusively that Valspar has the elasticity to withstand the terrific vibration of these powerful planes.

Other varnishes—good varnishes, too—crack from the vibration. And some varnishes that were tried actually flaked off and fluttered to the ground like autumn leaves!

The wonderful elasticity of Valspar Varnish is only *one* of the remarkable qualities that have caused it to be universally accepted as the standard airplane and seaplane varnish.

Our Airplane Department willingly places its experience at the disposal of all airplane and seaplane manufacturers.

To Purchasing Agents and Superintendents of Production: A valuable book full of information on airplane finishing will be sent free on request.

The Secret of Being a Convincing Talker

How I Learned It in One Evening

By GEORGE RAYMOND

"HAVE you heard the news about Frank Jordan?"

This question quickly brought me to the little group which had gathered in the center of the office. Jordan and I had started with the Great Eastern Machinery Co., within a month of each other, four years ago. A year ago Jordan was taken into the accounting division and I was sent out as salesman. Neither of us was blessed with an unusual degree of brilliancy, but we "got by" in our new jobs well enough to hold them.

Imagine my amazement, then, when I heard:

"Jordan's just been made Treasurer of the Company!"

I could hardly believe my ears. But there was the "Notice to Employees" on the bulletin board, telling about Jordan's good fortune.

Now I knew that Jordan was a capable fellow, quiet, and unassuming, but I never would have picked him for any such sudden rise. I knew too that the Treasurer of the Great Eastern had to be a big man, and I wondered how in the world Jordan landed the place.

The first chance I got, I walked into Jordan's new office, and after congratulating him warmly, I asked him to let me "in" on the details of how he jumped ahead so quickly. His story is so intensely interesting that I am going to repeat it as closely as I remember:

FREDERICK HOUK LAW

As educator, lecturer, executive, traveler and author few men are so well equipped by experience and training as Dr. Law to teach the art of effective speaking. His "Mastery of Speech" is the fruit of 20 years active lecturing and instruction in Eastern schools and colleges preceded by an education at Oxford Academy, Amherst College, Columbia University, The Teachers' College, Brown University and New York University. He holds the degrees of A.B., A.M. and Ph.D.

Dr. Law is the author of two novels, two books of poetry, and editor of six school textbooks. At present he is lecturer in English in New York University. Lecturer in Pedagogy in the Extension Work of the College of the City of New York, Head of the Dept. of English in the Stuyvesant High School and writer of the Weekly Lesson Plans for The Independent.

"I'll tell you just how it happened, George, because you may pick up a pointer or two that will help *you*.

"You remember how scared I used to be whenever I had to talk to the chief? You remember how you used to tell me that every time I opened my mouth I put my foot into it, meaning of course that every time I spoke I got into trouble? You remember when Ralph Sinton left to take charge of the Western office and I was asked to present him with the loving cup the boys gave him, how flustered I was and how I couldn't say a word because there were people around? You remember how confused I used to be every time I met new people? I couldn't say what I wanted to say when I wanted to say it; and I determined that if there was any possible chance to learn how to talk I was going to do it.

"The first thing I did was to buy a number of books on public speaking, but they seemed to be meant for those who wanted to become orators, whereas what I wanted to learn was not only how to speak in public but how to speak to individuals under various conditions in business and social life.

"A few weeks later, just as I was about to give up hope of ever learning how to talk interestingly, I read an announcement stating that Dr. Frederick Houk Law of New York University had just completed a new course in business talking and public speaking entitled 'Mastery of Speech.' The course was offered on approval without money in advance, so since I had nothing whatever to lose by examining the lessons, I sent for them and in a few days they arrived. I glanced through the entire eight lessons, reading the headings and a few paragraphs here and there, and in about an hour the whole secret of effective speaking was opened to me.

"For example, I learned why I had always lacked confidence, why talking had always seemed something to be dreaded whereas it is really the simplest thing in the world to 'get up and talk.' I learned how to secure complete attention to what I was saying and how to make everything I said interesting, forceful and convincing. I learned the art of listening, the value of silence, and the power of brevity. Instead of being funny at the wrong time, I learned how and when to use humor with telling effect.

"But perhaps the most wonderful thing about the lessons were the actual examples of what things to say and when to say them to meet every condition. I found that there was a knack in making oral reports to my superiors. I found that there was a right way and a wrong way to present complaints, to give estimates, and to issue orders.

"I picked up some wonderful pointers about how to give my opinions, about how to answer complaints, about how to ask the bank for a loan, about how to ask for extensions. Another thing that struck me forcibly was that, instead of antagonizing people when I didn't agree with them, I learned how to bring them around to my way of thinking in the most pleasant sort of way. Then, of course, along with those lessons there were chapters on speaking before large audiences, how to find material for talking and speaking, how to talk to friends, how to talk to servants, and how to talk to children.

"Why, I got the secret the very first evening and it was only a short time before I was able to apply all of the principles and found that my words were beginning to have an almost magical effect upon everybody to whom I spoke. It seemed that I got things done instantly, where formerly, as you know, what I said went 'in one ear and out the other.' I began to acquire an executive ability that surprised me. I smoothed out difficulties like a true diplomat. In my talks with the chief I spoke clearly, simply, convincingly. Then came my first promotion since I entered the accounting department. I was given the job of answering complaints, and I made good. From that I was given the job of making collections. When Mr. Buckley joined the Officers' Training Camp, I was made Treasurer. Between you and me, George, my salary is now $7500 a year and I expect it will be more from the first of the year.

"And I want to tell you sincerely, that I attribute my success solely to the fact that I learned how to talk to people."

******

When Jordan finished, I asked him for the address of the publishers of Dr. Law's Course and he gave it to me. I sent for it and found it to be exactly as he had stated. After studying the eight simple lessons I began to sell to people who had previously refused to listen to me at all. After four months of record breaking sales during the dullest season of the year, I received a wire from the chief asking me to return to the home office. We had quite a long talk in which I explained how I was able to break sales records—and I was appointed Sales Manager at almost twice my former salary. I know that there was nothing in me that had changed except that I had acquired the ability to talk where formerly I simply used "words without reason." I can never thank Jordan enough for telling me about Dr. Law's Course in Business Talking and Public Speaking. Jordan and I are both spending all our spare time making public speeches on war subjects and Jordan is being talked about now as Mayor of our little Town.

So confident is the Independent Corporation, publishers of "Mastery of Speech," Dr. Law's Course in Business Talking and Public Speaking, that once you have an opportunity to see in your own home how you can, in one hour, learn the secret of speaking and how you can apply the principles of effective speech under all conditions, that they are willing to send you the Course on free examination.

Don't send any money. Merely mail the coupon or write a letter and the complete Course will be sent, all charges prepaid, at once. If you are not entirely satisfied send it back any time within five days after you receive it and you will owe nothing.

On the other hand, if you are as pleased as are the thousands of other men and women who have used the Course, send only $5 in full payment. You take no risk and you have everything to gain, so mail the coupon now before this remarkable offer is withdrawn.

MARTIN BOMBER

The Bomber Performance Demonstrates Military Supremacy

The Martin Plane is First to Fulfill Commercial Requirements

MARTIN U.S.A.

Our Freighter and 12-Passenger Airplane soon to be announced

THE GLENN L. MARTIN COMPANY
CLEVELAND
Contractors to the United States Government

(*Continued from page* 1041)

while the contract should not have been made verbally, it was so made probably because the people who made it did not know what the regulations were, that the service had been obliged to call in many people without military experience to assist in this work; and that the contract which had been made with the Packard Company was a perfectly regular contract but now drawn up in the regular way.

Major Howard Elliott, Disbursing Officer of the Aviation Section of the Signal Corps, testified that while Section 653 of the Army Regulations provides that:

> "Every order issued by any military authority which may cause an expenditure of money in a Staff Department will be given in writing."

The memorandum consisting of the resolution passed by the Aircraft Production Board setting aside $250,000.00 for this work, was construed as an order because of an erroneous practice that had sprung up.

Major Coleman (from whose written memorandum a quotation has been made) testified at the Hughes inquiry that the resolution referred to was considered authority for the payment of the money mentioned in it; that there were other cases in which money had been set aside in that manner; and that while the regular practice requires that the Bureau should place written orders, that was not considered necessary.

Lieutenant Colonel A. C. Downey, of the Signal Corps, testified that while it was a bad practice to pay out money in cases where there had been no written orders, it was the practice in vogue at that time in jobs "where they wanted to rush things through," simply to request that a given amount of money be set aside, and when set aside, no written orders were placed; and when the vouchers were paid, these vouchers, under the practice, took the place of written orders, that this had been done in hundreds of cases, but that he did not remember any case in which it had been done where a large amount of money was involved.

Under these conditions it is not the opinion of this office that an officer entering the Army from civil life, as did Colonel Deeds, following a practice which he found in vogue in the office, should be court-martialed for an act of the character here involved, which, as found by Judge Hughes in his report, did not defraud the Government, and was not intended so to do.

This office therefore recommends that court-martial proceedings should not be instituted against Colonel Deeds on account of this transaction because: (1) the approval of the voucher in question did not involve any attempt to defraud the Government; (2) as found by Judge Hughes, it did not defraud the Government; (3) the verbal agreement upon which the voucher was paid, as found by Judge Hughes, was fair from the standpoint of the Government.

Conclusion

6. The conclusion of this office is, therefore that Colonel Edward A. Deeds should not be tried by court-martial on account of any of the transactions discussed in this memorandum.

The justice of the conclusion thus reached by this office finds confirmation in the following language taken from a letter from Hon. John D. Ryan, Director of the Air Service, addressed to the Secretary of War under date of November 13, 1918:

"I feel, as I stated in a former letter to you, that Colonel Deeds performed a great service in expediting the work on the Liberty motor. If he had followed strict regulations and kept within them in the expenditure of money for the production of the first of these model engines we would probably not have had any quantity production yet. I feel that the patriotic service rendered to the Government and the sacrifice made in connection therewith by Colonel Deeds outweighed any technical violations that might have occurred, and considering the conditions under which this work had to be done, if the aircraft was to take any part in the war within a reasonable time, I think commendation instead of court-martial should be Colonel Deeds' reward."

7. There are attached here to the following papers: (a) the memorandum from the Secretary of War referring the matter to this office for report and recommendation, together with the papers attached thereto, (b) endorsement from this office dated November —, 1918, returning to the Adjutant General a memorandum from the Inspector General's Department, dated November 2, 1918, and the accompanying papers; (c) memorandum submitted by this office under date of November 11, 1918, expressing its conclusion based upon the Hughes report; (d) memorandum for Honorable John D. Ryan, Director of Air Service, signed W. W. Montgomery, Chief Advisory and Consulting Department, dated November 11, 1918; (e) memorandum submitted to this office under oath and signed B. F. McCann, attorney for Colonel Edward A. Deeds; (f) affidavit of H. E. Talcott, former business associate of Colonel Deeds; (g) memorandum submitted to the Secretary of War by John D. Ryan under date of November 13, 1918; (h) letter from Major E. A. Coleman, Disbursing Officer, Bureau of Aircraft Production, to this office under dated of November 25, 1918, with exhibits; (i) copy of the official Bulletin, dated February 21, 1918, containing the newspaper article criticized by Judge Hughes in his report; and (j) affidavit of Edward A. Deeds, dated November 20, 1918, together with chronology and copies of correspondence submitted by Colonel Deeds; (k) letter to the Secretary of War from Hon. John D. Ryan, dated November 6, 1918.

AERIAL AGE WEEKLY

Vol. 8, No. 22 FEBRUARY 10, 1919 10 CENTS A COPY

A fleet of 212 Curtiss J. N. training planes on a two-hour flight over San Diego, California, from Rockwell Field

Future Air Traffic and the Necessary Regulations to Govern It

The King-Bugatti Aviation Engine Described

UBLISHED WEEKLY BY THE AERIAL AGE COMPANY, INC., FOSTER BUILDING, MADISON AVENUE AND FORTIETH STREET, NEW YORK CITY

Storm Does Not Halt the STANDARD Mail Plane!

DAY in and day out, regardless of weather conditions, the fleet of postal planes built by the Standard Aircraft Corporation carries the air-mail between New York, Philadelphia and Washington.

Uninterrupted flights have been made through storms that have practically halted all highway travel. On more than one occasion landing fields have been so rain-soaked that the planes had to rise from mud up to their hubs.

That the fleet has stood this gruelling test perfectly is another demonstration of the sturdiness and reliability of "STANDARD" airplanes.

"SERVICE"

"NORMA"
PRECISION
BALL BEARINGS
(PATENTED)

In normal times, salability may be placed before serviceability. But in times like these, serviceability comes into its own—salability becomes a minor consideration. To "make good"—to be adequate—to bear a full share of the national burden—these are the big essentials now. And the machines which today most conclusively prove their serviceability will, in normal times, be the ones that find the readiest market.

In peace-time, as in war-time, "NORMA" Ball Bearings are proving their serviceability in the ignition apparatus and lighting generators used on the airplanes, cars, trucks, tractors and power boats which are meeting the service demands on land, at sea, and in the air, at home and abroad.

Be SURE. See that your Electrical Apparatus is "NORMA" Equipped.

EVERY FIRST CLASS AEROPLANE REQUIRES A RETRACTABLE CHASSIS

Jas. Vernon Martin

Originator in America of the Only Type of Aeroplane Now in General Use, the Tractor Biplane

Offers the services of his highly skilled aeroplane engineering organization to existing and prospective aeroplane companies for guidance as to what to build and how to build it.

Special experts in every phase of aerodynamics and aeroplane design furnished in a consulting capacity.

Martin has designed the most efficient planes in three classes during the war and in addition to the following efficiency features his organization can furnish complete information and aerodynamic data on types now available for commercial work.

The following aeroplane efficiency features will be discussed in succeeding announcements:

The Retractable Chassis
The K-bar Cellule Truss
Neutralized Symmetrical Wing End Ailerons
Aerodynamic Aeroplane Control
Shaft Drive Bomber Transmission
Aerofoil Type Fuselage
Rubber Strand Shock Absorbing Wheel
Shock Absorbing Rudder
Shock Absorbing Pontoon Supports

The Martin features are fully protected by domestic and foreign patents and are available to the aircraft industry at exceedingly small royalties.

Contractor to United States Army and Navy

MARTIN AEROPLANE FACTORY

Devoted exclusively to the engineering development of new types. Elyria, Ohio.

FUTURE AIR TRAFFIC AND NECESSARY REGULATIONS TO GOVERN SAME

Address delivered by Alan R. Hawley, President of the Aero Club of America, at the Convention of the National Rivers and Harbors Congress, held at Washington, D. C., February 5th, 6th and 7th, 1919

AIR traffic will be with us during the coming year, partly as a result of the establishing of aerial transportation lines by private interests and greatly as a means of salvaging the billion dollars' worth of Army and Navy equipment, and employing the 28,000 pilots and 300,000 men being discharged by the U. S. Army and Navy Air Service.

There are three leading aeronautic problems of national importance to be solved, as follows:

(1) The U. S. Army, according to the Senate report, spent in the last two years $1,672,000,000 in aircraft, parts, aerodromes and aeronautic equipment of different kinds. The Navy spent approximately $250,000,000 for aeronautics. Since these figures were made public the figures may have changed somewhat through cancellations of orders. But it is a fact that the Army Air Service has thousands of aeroplanes, about 20,000 Liberty motors, about 7,000,000 yards of aeroplane linen, 30,000,000 feet of aeroplane spruce and general equipment and accessories for sale, for which the Government has paid about $800,000,000. The Air Service has, besides, thirty aerodromes and aviation and balloon depots, two-thirds of which, according to reports, will have to be abandoned at a loss of tens of millions of dollars. The Navy, also, has a substantial lot of aeronautic equipment to dispose of.

(2) The Army and Navy have a total of about 30,000 aviators and balloon pilots in service, each of whom cost not less than $10,000 to train, and about 300,000 motor and plane skilled mechanics and other trained assistants. A few thousands of the pilots have already been demobilized—and they are looking for positions. The first few thousand mechanics who were demobilized found positions elsewhere. The rest are also looking for positions. The Aero Club of America and the Aerial League of America and the aeronautic publications, *Flying*, AERIAL AGE WEEKLY and *Air Power* are flooded with applications for positions. The Peace Program of the Army and Navy plans to use only less than 2,500 pilots and less than 15,000 men. The Army Bill, now before Congress, limits the Air Service to less than 2,000 commissioned officers. The Navy Bill, now before Congress, provides for the retention of only 350 aviators in the Navy, out of the present 10,000 aviators in service.

(3) Now that we have aeroplanes capable of carrying fifty passengers and dirigibles capable of carrying 80 tons of useful load, and it is a common occurrence for aircraft to fly 600 or 800 miles across country between sunrise and sunset, it is necessary to draft regulations to govern aerial navigation and air traffic.

Possible and Logical Solutions of These Problems

Solution to Problems Nos. 1 and 2

There are two solutions to the first problem. The first solution, which does not seem to be the best for the interest of the Government or the country, is to sell the aeroplanes, motors and equipment for whatever sum can be realized, and to abandon the aerodromes. It is doubtful whether this plan would bring back to the Government ten per cent of what it has paid for this equipment.

The worst feature of this plan would be that the dumping on the market of all this equipment will practically kill the aeronautic industry for years and will not solve the problem of finding positions for the 28,000 aviators and 300,000 trained personnel being discharged by the Army and Navy Air Service.

Another bad feature of this plan would be that in case of emergency the Government would find itself without anything, because the personnel would have been disbanded, and the aeroplanes and motors would have been scattered all over the world, and would be out of reach or in bad condition, unfit for service.

The second and best solution to this problem is to organize a Government Aerial Transport Corporation, similar to the Grain Corporation, which shall take over and use for aerial transportation all the aeroplanes, motors and equipment not needed by the War and Navy Departments. The Grain Corporation, it will be recalled, was capitalized at $50,000,000, all the stock being owned by the Government. It was operated by a civilian board of directors, who knew their business and were not hampered in any way by official red tape. This board purchased, distributed and transported all grain during the period of the war and was successful in every way and met with general approval.

This Aerial Transport Corporation would undertake to utilize the aeroplanes, motors, equipment and aerodromes to the best advantage and to the best interests of the Government.

There are 380 cities in the United States that have asked the co-operation of the Aero Club of America and the Aerial League of America to establish air lines to carry passengers, express and mail. This can be considered as public demand for aerial transportation.

It would be a great advantage and would relieve railroad congestion, if all first class mail could be carried by aeroplanes. The Post Office is ready to establish aerial mail lines throughout the country and needs hundreds of twin motored aeroplanes to carry this plan into effect.

Aerial ferries could be established on waterways throughout the United States. Aerial ferries across Long Island Sound, from Newport to Block Island, Cape Charles to Norfolk, Key West to Havana, across the Mississippi, etc., and air lines could, in fact, be established wherever there are waterways, as well as between cities on land. These lines would only be established where there are no such lines operated by private interests and, if it is thought best, the lines once in operation, or the equipment for operating the lines, can be sold to private interests. Likewise, the 30,000,000 feet of spruce and 7,000,000 yards of aeroplane linen, and the tons of castor beans could be sold when the opportunity occurs. It would be wiser to use this material rather than sell it at a fraction of its cost which would create industrial or labor problems by swamping the market.

To establish these air lines or to supply suitable planes to the Post Office, it would probably be necessary to get larger or special aeroplanes. These could be manufactured by established manufacturers, using the Liberty motors, the aeroplane spruce, lines, wheels, wire, turnbuckles, instruments, etc., which the Government has on hand.

In other words, this corporation would be the clearing house in charge of utilizing the $800,000,000 of idle aeronautic equipment to the best advantage and best interest to the country.

By establishing an Aerial Transport Corporation and investing $50,000,000 the Government can;

(a) Salvage a good percentage of the $800,000,000 of idle aeronautic equipment which it has on hand.

(b) Solve the problem of employing a large number of the aviators and trained personnel that are thrown in idleness by demobilization.

(c) Will utilize the military and naval aerodromes and depots which otherwise must be abandoned, at a great loss. If kept in use these aerodromes and hangars may later be sold at fair prices to private concerns, which will, no doubt, be formed during the coming year, to operate aerial transportation lines.

(d) It will keep all this aeronautic equipment and trained personnel under control, so it can be taken over by the Army and Navy in case of emergency.

(e) The Corporation can undertake, if found advisable, to arrange to establish air lines in South and Central American countries, the governments of which are anxious to have aerial transportation to solve their problems of transportation and intercommunication and would welcome some arrangement which would supply them with these air lines in the near future.

(f) It would preclude the possibility of all this aeronautic equipment deteriorating in storehouses while the Government has to pay rental for storing it.

(g) It will also eliminate the huge economic waste that will follow if special materials such as aeroplane spruce and linen must be used for purposes for which ordinary materials would do.

Regulations to Govern Air Traffic

The third problem, that of drafting regulations to govern air traffic, is complex, mainly because the subject is new.

Air traffic is all interstate and international traffic. Aerial transportation is very fast transportation. Aviators carry the mail between New York and Washington daily in a little over two hours. The first trips have shown that the mail will be carried between New York and Chicago in about seven hours. By a system of relays of planes, going at 120 miles an hour, it would be possible to send mail from New York to San Francisco within one day's daylight. This is made possible by the fact that Pacific coast time is three hours slower than Eastern time.

Three classes of regulations will be necessary to regulate aerial navigation, as follows:

(1) International regulations, which will regulate international aerial navigation and will determine whether there shall be freedom of the air or not. These regulations will be decided by international agreement.

(2) National regulations to govern interstate air traffic, based on the regulations which govern railroad, marine and highway interstate traffic. This will involve the registration of aircraft under the rules of the Department of Commerce, just as vessels are registered by the Steamboat Inspection Service under the rules of the Department of Commerce.

Aircraft are really ships navigating in a sea of air. As soon as permanent air routes are established, aircraft will operate between stations like ships operate between ports or trains operate between stations. Hence the possibility of applying the interstate traffic regulations and the Steamboat Inspection Service's rules of registration and inspection.

The British Aerial Transport Committee, which has made a thorough study of the subject, has drafted lengthy regulations, which are somewhat restrictive in nature, for military reasons, but which can be used as a basis for drafting national regulations to govern interstate air traffic.

(3) Regulations to govern aerial sports and competitions. These regulations are drafted by the International Aeronautic Federation, which is composed of the delegates of the National Aero Clubs of the nations of the world. The first regulations were drafted by the Federation in 1905, and all aerial sports and competitions are governed by them. These regulations have been recognized by the courts. They have supported the verdict of national aero clubs, representatives of the Federation, which fined and suspended aeronautic organizations for disobeying the rules of the Federation.

The regulations of the Federation governing aerial sports and contests, are accepted and recognized by 38 countries.

What Other Countries Are Doing

Unless prompt action is taken to establish air lines, the United States, the country of Langley, the Wrights, Curtiss, and other pioneers who helped to give the world the practical aeroplane and hydroaeroplane and flying boat, will again be backwards in aeronautics. Failure to act on time on Aerial preparedness resulted in our being too late aeronautically to be effective in the war. The reports from headquarters printed on December 24th, stated that on November 11th, when hostilities ceased, the American Expeditionary Forces had only 102 American-made aeroplanes at the front. Several hundred more were on the way, but had not yet reached the front. The rest of the planes being used by American aviators were of French or British make.

We paid an enormous price for our unpreparedness, and this should teach us a lesson.

Some of the air lines proposed by other countries are as follows:

Denmark, Norway and Sweden have formed companies for the development of International Commercial Aeronautic Transportation, with a capital of $5,000,000 paid in.

The purpose of the Norwegian company is to establish a rapid transit passenger carrying line which will eventually reach as far as Trondhjem. The first step in this direction will be a line from Christiania to Christiansand. It is the intention of the Norwegian Air Line Company to start with six large flying boats. The trip from Christiania to Christiansand at the present time takes about 18 hours, and the same distance could be covered by aeroplane in about three hours.

It is also the intention of the air line company to establish reserve stations about 30 or 40 miles apart. Three of these reserve stations to have a reserve aeroplane. The other stations will simply keep the most necessary supplies—gasoline, oil, etc. It is the intention of the company-to keep two planes running and four in reserve for this first route.

Places have been made for permanent landing places all the way to Trondhjem, and when these planes are in operation they will also operate about twenty-six flying boats.

Besides the Norwegian Air Line there is also established an International Line to the west coast of Norway, to Scotland from Christiania, to Gottenburg, and to Copenhagen.

It was the intention of the Norwegian company to have this line started as early as May of last year, but on account of the war it was impossible to secure the necessary planes.

In Canada the business men of Charlottetown, Prince Edward Island, have decided to form a company to organize and maintain an aerial mail service with the mainland, and in order to urge its cooperation in the development of aeroplanes, a deputation of the Canadian Division of the Aerial League of the British Empire waited upon the Government on December 9th, when members of the Cabinet expressed themselves as being heartily in sympathy with the objects of the League.

In Italy mail is being carried from Genoa to Naples and from the mainland to the Island of Sicily and extensive plans have been made by Mr. Caproni, one of the foremost constructors of large machines for commercial development in Italy.

In France the Government authorities are sending food and supplies by aeroplane to places in the devasted districts of Northern France that cannot be reached in any other way as well, and they have utilized for this purpose the large bombing machines and 70 tons of food and supplies are being delivered daily, according to recent reports.

Many companies are also being formed for the purpose of promoting commercial aviation.

The London-Paris passenger air line is already in operation. Some of the proposed routes are:

(1) From London to Salonica, by way of Nice, Rome Brindisi and Vallona.

(2) Between Australia and London, proposed at a meeting of business men at Sydney on October 2nd. The aerial service would take 150 hours for the trip.

(3) From London to everywhere, proposed and being carried out by Holt Thomas, the managing director of the British Aircraft Manufacturing Company, who explains his plans as follows:

"We are opening air routes all over the world in conjunction with local companies. In France we will operate in connection with a French company, and already arrangements for such a service are practically completed in Norway, Denmark, Italy, India and Africa. Later we will extend the service to Japan, China and the West Indies."

(4) From India to other parts of the British Empire, proposed by the Government of India as a postal service.

(5) From India, via Alexandria, and the Red Sea to Australia, via Cape Town, to New Zealand.

(*Continued on page* 1085)

THE NEWS OF THE WEEK

Sturtevant Company Planning Airship Line

The Manufacturers' Aircraft Association announced that one of its members was investigating the feasibility of establishing passenger service by dirigible between New York and Chicago. J. M. McElroy, chief engineer of the Sturtevant Airplane Company, of Boston, and Noble Foss, son of ex-Governor Foss of Massachusetts, estimate that a service with four airships can be established at an initial cost of about $5,000,000.

Preliminary plans for the aircraft to be used include carrying capacity for twenty-five passengers and ten members of a crew, and it is pointed out in the announcement that development of this type of airship is entirely feasible, inasmuch as dirigibles, as well as aeroplanes, have carried more persons than is proposed. Their first estimate is that it would cost about 65 cents a mile to carry each passenger, and that the fare probably would be more han $520 to Chicago. This estimate follows closely the figures of the report of the Civil Aerial Transport Committee of Great Britain and other organizations have made investigations.

"The ships would be of the Zeppelin type, rigid housing, and multiple compartment construction," says the announcement. " Helium gas would be used, thus removing the danger of inflammability that now exists with the use of hydrogen. Recent figures give a cost of 10 cents per cubic foot, which would amount to $50,000 for the initial inflation of 500,000 cubic foot capacity ship. The loss due to leakage is said to be less than that of hydrogen, and there are at least two plants in this country built especially for the production of this gas, which would insure an adequate supply.

"Cabin accommodations, under the plans, would be in the interior of the housing structure and in the centre of the ship, connected to the top of the structure, which would be a housed-in observation deck, by a spiral tubular staircasing. The cars would be swung out from the hull to give clearance for the propellers.

"The ship would be approximately 425 feet long and 45 feet in diameter. Its engines would total 1,200 horsepower. The bag would have 650,000 cubic foot capacity, providing a gross lift of 20 tons at sea level, which would mean approximately 10 tons useful lift. It would be capable of flying 70 miles an hour, and a trip to Chicago could be made comfortably in less than twelve hours.

"The power plant would consist of twin engines, side by side, driving through gears a central stub shaft mounting a variable pitch air screw. This arrangement would centralize the power and allow operation of one or both motors in the car to meet conditions of adverse or favorable winds, or fast or slow speeds. The engines would be heavier constructed than the typical aeroplane motor, with the reliability and endurance of the automobile type. Gasoline and oil tanks would be located along the keel and fuel fed to the engines through an automatic pressure system that would insure even loss in tanks, so as not to affect the balance of the ship."

Mr. McElroy believes that the greatest difficulty to be overcome in handling these air liners will be in landing them, but he asserts that problem can be solved. Passengers could be lowered in a cage, he thinks, or heavy windlasses could ease the craft into a dock. Another suggestion is that a dock floating in the air be devised so that he changes of the wind would not hamper a landing. This dock would be anchored only at one end.

As proof of their ideas that the use of the type of airships is feasible the promoters point to the successful flight of a German ship to East Africa, a journey of more than 7,000 miles, without reprovisioning. The last successful flight cited is that of the United States Navy dirigible C-1 from Long Island to Key West. From this preliminary type larger ships for oceanic flights probably could be developed, the announcement says, in pointing out that it is more desirable to carry out the preliminary experiments over land.

Manufacturers To Have Large Exhibits at Aero Show

The committee in charge of the arrangements for the Aero Show to be held at Madison Square Garden and the 69th Regiment Armory from March 1st to March 15th, is laying particular stress on the artistic arrangement of the Exhibits. Practically all aircraft manufacturers will be represented.

It is known that the Dayton-Wright Airplane Company, of Dayton, O., will have two machines on view, one of which, it is declared, will be novel in design and indicative of the new mode of travel. The Curtiss Aeroplane & Motor Corporation of Buffalo, N. Y., has reserved space for four planes and seaplanes. The L. W. F. Engineering Corporation, of College Point, L. I., is to exhibit three: the Aeromarine Plane and Motor Company, of New York City, will have one special design on display. Three Thomas-Morse models from the factory at Ithaca are to be placed as well as one from the Burgess Company, of Marblehead, Mass. The Gallaudet Aircraft Corporation of East Greenwich, R. I., is to show two of its productions.

While most of the foreign exhibits will be made directly by the United States government, there is considerable interest in the model to be shown by Pomilio Brothers, Italian manufacturers, with offices in New York.

The mail carrying planes used on the New York to Washington route will be on display.

One of the ingenious and useful devices to be exhibited is an improved type of aeroplane compass, which has underneath it a special magnet which counteracts any local magnetic attraction and makes long distance flights possible without ground observation.

Information just received from Washington indicates that balloons are to form no small part of the exposition. The army has a considerable number of these, of various types and sizes, ready to display. It has been suggested that a Caquot be inflated in Madison Square Garden. Army engineers who have figured on this work say that it can be done, although the balloon measures 96 by 30 feet. Another example is the famous French barrage balloon, 30 by 15 feet. It was this type of balloon that entered prominently into the defense of Paris.

Flew 2,900 Miles in 28 Hours 50 Minutes

Houston, Texas, Jan. 27.—Two De Haviland Liberty-motored planes, which left Ellington Field December 14 for a mapping and aerial observation flight from the Gulf of Mexico to the Great Lakes, returned to the field yesterday after covering 2,900 miles in twenty-eight hours and fifty minutes, flying time.

At the outset the two planes encountered bad weather and were detained ten days at St. Louis, nine days at Indianapolis, and six days at Detroit. During the trip they ran into temperatures 10 degrees below zero, heavy rains, and snow.

Aero Club of Northwest Arranging for Landing Places

Seattle, Washington.—The Aero Club of the Northwest has been conducting an active campaign for the establishment of air routes in Washington and Oregon. Inquiries have been conducted in the leading cities to ascertain the landing facilities for aeroplanes, hydroaeroplanes, and seaplanes available, and in cases where unavailable, what civic body would be interested in the establishment of aerial landing places.

The Board of Trustees of the Aero Club of the Northwest have passed a resolution making eligible to special membership all men in the aviation service, both Army and Navy, who have won their wings.

Great Britain Restricts Imports

Washington, D. C., January 29.—In order to facilitate the rehabilitation of her industries, and restore the balanced commercial relationships existing in pre-war days, the British Government has decided on certain important restrictions of imports. Those of special interest to aeronautic and allied industries are: manufactures of aluminum, metal baths of all kinds, woodworking machinery of various kinds, pictures, prints, photographs, weighing machines and balances of all types.

Major Macauley Completes Transcontinental Flight

Americus, Ga.—Major Theodore Macauley has completed his transcontinental flight and started on his return trip from the Atlantic coast to Taliaferro Field, where he is commanding officer, on January 26.

Major Macauley flew from Taliaferro Field to San Diego, Cal., then to Arcadia, Fla.

600 Pound Seaplane Makes Speed Record

The first scout hydroaeroplane detailed at the Naval Air Station, Anacostia, with speed capacity, was tried out recently.

Lieut. U. G. Shipman, who has been flying for seven years, piloted the plane in its first flight down the Potomac, attaining speed of 150 miles an hour, an innovation in the speed record of a hydroaeroplane.

The hydroaeroplane weighs approximately 600 pounds, and is propelled by a 100 horse-power motor.

Other trial flights will be made over Washington before the featherweight seaplane is shipped to a Western station for future experimental purposes.

United Aircraft Engineering Corporation Buys Canadian Equipment

The United Aircraft Engineering Corporation of New York City has purchased a large part of Canada's air service equipment.

The purchase included approximately 400 Curtiss JN-4 biplane, about 900 ninety-horsepower Curtiss OX motors and thousands of spare parts, struts, propellers, wires, wings and fuselages. In conjunction with this equipment the United Aircraft Engineering Corporation intends to use a new monoplane, the Stout, an invention of William B. Stout, of Dayton, Ohio, which the corporation is developing. This machine is being built in two types, a weight carrier and a single seater.

The three leading American Aces, who have just returned from France. Left to right: Lieut. P. F. Baer, Capt. Eddie Rickenbacker and Capt. Douglas Campbell

Fire at Far Rockaway Air Station

The explosion of gasoline in a tank on which repairs were being made with a blow torch in one of the largest hangars at the Naval Air School, Rockaway Beach, started a fire that destroyed the hangar and another aircraft shed adjoining and partly burned five small auxiliary buildings.

It was reported, but not officially admitted, that four large seaplanes and eight small Spads housed in the two hangars were destroyed.

Rickenbacker and Meissner Return

The White Star liner *Adriatic* brought in on January 31 Capt. Eddie Rickenbacker and Major James A. Meissner, two of the most intrepid yet unpretentious stars in the American aviation service, but all the committees that wanted to welcome them were debarred from going aboard the ship by order of the War Department.

Capt. Rickenbacker, of Detroit, was head of the "Hat in the Ring Squadron," otherwise No. 94, officially credited with destroying twenty-six Boche machines.

Major Meissner, of Flatbush, put eight Hun planes out of business. Flatbush was disappointed because it could not get anywhere near the Major, and several automobile and aero organizations protested when they learned that they would have to talk with Capt. Eddie over the rail.

Ban on Promotions Explained

Washington, D. C.—Secretary of War Baker has made a reply to the many critics of the policy of the War Department in prohibiting promotion to officers. Appointments are made only when vacancies exist, and will continue to be so made. However, when the demobilization orders were issued, there was created a surplus of officers of every grade, and hence no further promotions were possible. There is no contemplation of change of this policy.

Aerial Research Emphasized by Col. Bane

Washington, D. C.—In discussing the Army Bill before the House Committee on Military Affairs, Col. T. H. Bane, chief of the engineering work of the Air Service, laid great emphasis upon the necessity of carrying on all manner of experimental and research work in the aviation field, both with regard to planes and motors.

Col. Bane stated that it will be the policy of the experimental and research bureau to have exact working details, including drawings and blue prints, of the most highly developed aeroplanes of each class and the most highly developed and most satisfactory motor for each type of machine, so that in the event of the country being involved in war, immediate production of all types may be inaugurated. The amount of appropriation called for in the bill under consideration for such work is $10,663,280.

Regarding the purchase of flying fields, it was pointed out before the committee that $4,000,000 would be sufficient to purchase all fields which the Government for the present is not planning to place in active service. In view of the fact that $65,000,000 worth of equipment has been installed, it would be a measure of great economy. Fourteen fields of the thirty in operation during the war are to be maintained.

FONCK TO BE GUEST AT AERO CLUB BANQUET

Lieut. Rene Fonck, ace of all aces, who has an official record of 75 German machines to his credit, and an unofficial record of 125 machines, and who on two occasions has brought down six machines in one day, has been granted permission by the French Government to attend the 13th Annual Banquet of the Aero Club of America, and will be the guest of honor.

Lieut. Charles Nungesser, second in the list of French aces and Robert Esnault Pelterie, President of the Aeronautic Industries Association of France, are accompanying Lieut. Fonck and will be present at the Banquet.

Among the other aces expected to be present are, Colonel William A. Bishop, VC., D.S.O., M.C., D.F.C., Lieut. Colonel William Thaw, Captain Edward V. Rickenbacker, Major James A. Meissner, Captain Arthur J. Coyle, in command of the 1st Aero Squadron and one of the 300 aviators trained by the Aero Club of America in 1915-1916, and as many of the American Aviation Officers from the front as are free to attend on that evening.

Rear Admiral Robert E. Peary has accepted an invitation to speak upon "Exploration by Aeroplane" and the opportunity for great aerial transportation systems to be extended all over the United States.

Major General Charles T. Menoher, Director of the Air Service, will speak on Military Aeronautics, and Rear Admiral Bradley A. Fiske, U.S.N., retired, will speak upon recent developments in maritime Aeronautics.

Mr. John Hays Hammond, Jr., will speak on the subject "Polar Aero Radio Survey."

The Honorable Fiorello H. La Guardia, Major in the Air Service and Member of Congress, will speak upon the wonderful developments in aviation in Italy, and an invitation has been extended to Signor Gianni Caproni, who is expected to arrive in this country.

Col. Henry Arnold, Chief of Air Service on Coast

San Diego, Cal.—Col. Henry H. Arnold, one of the oldest American aviators in point of service, has been made military aeronautical officer for the California district. He will maintain offices at Coronado for himself and his staff.

Restrictions on Aeroplane Exhibitions Withdrawn

President Wilson has issued, under date of December 16, 1918, a proclamation revoking the proclamation of January 1, 1918, which imposed restrictions upon private aeroplane exhibitions in the United States.

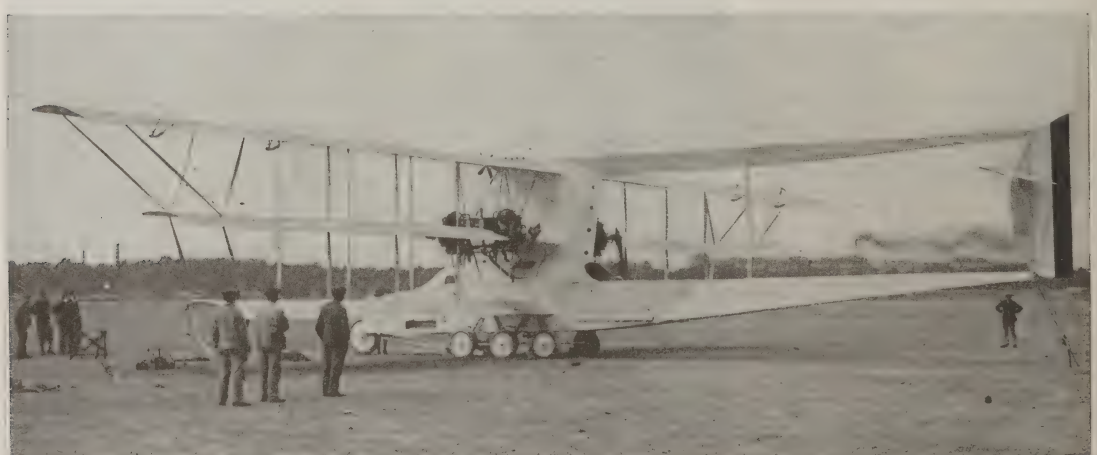
New R. M. A.'s

The following named officers are rated as Reserve Military Aviators: Second Lieuts. Robert W. Catlin, Richard C. Sogge, Ernest W. Force, Arnold B. Henderson and Edmund Pincoffs.

Flying for Discharged Aviators

The Division of Military Aeronautics has announced that members of the Officers' Reserve Corps who are R. M. A.'s may be authorized upon application, at the discretion and at the convenience of the commanding officers, to make flights in Army aeroplanes. It is pointed out, however, that cross-country flights should not be permitted and that the regular training of pilots should not be interfered with.

A scheme providing for the use of ships by Reserve Officers is in preparation as part of the permanent organization of the Air Service, but cannot be put into effect at the present time.



Geodetic Survey Planning Aerial Mapping

The following letter was received by the Standard Aircraft Corporation officials from George Otis Smith, director of the U. S. Geological Survey.

"The Geodetic Survey in cooperation first with the Council of National Defense and later with the Engineer Corps of the army has for more than a year been engaged in the development of a method of mapping, which involves the use of aeroplane photographs. The Geodetic Survey has not yet employed this method in its own work, but the investigations along this line are being continued."

Air Service History to be Written

Washington, D. C.—Lieutenant H. W. Heintz, Air Service, has been detailed to the Aeronautical Information Branch of the Executive Section, D.M.A., with the duty of compiling the history of every Aero Squadron that has served in American Expeditionary Forces. The originals of these documents will be filed in Washington and a set will be forwarded to Information Section, Air Service, A.E.F.

A Voisin Triplane with four motors

The AIRCRAFT TRADE REVIEW

A. E. J.

Curtiss Production Record

The figures for Curtiss motor and plane production have recently been made public. The Curtiss Company produced approximately 80% of the motors used on training planes. The Hammondsport plant made and shipped 5,474. At the Willys-Morrow plant in Elmira, 6,491 Curtiss motors are made.

At the Churchill street plant, Curtiss workmen built a total of 5,181 out of the 7,200 training planes of all types furnished the United States government.

Curtiss flying boats were largely used by the navy. Curtiss workmen built 90% of all furnished the United States and a large percentage of those used by our Allies. At the North Elmwood plant they built 673 of the small type known as the H-S-2-L. Four F-5's among the largest flying boats in the world were completed at the time of armistice. The Austin street plant built 149 gigantic flying whales of the H-16 type for the United States navy and the British admiralty. The total number of naval craft built exceeds 1,026.

And while this work was under way, the Curtiss Company designed and perfected the K-12 and K-6 motors, new types for aviation, and the most efficient the world has yet seen. They built also the greatest flying boat in the world, the NC-1, which recently flew with 50 passengers aboard.

B. F. Goodrich Co. Has Profitable Year

In a preliminary report of the B. F. Goodrich Company, manufacturers of rubbers goods, for the year 1918, net sales are shown to have been $123,400,000 and the net profits $15,000,000, before making provisions for Federal income and excess profits taxes, but after allowances for maintenance, charges, depreciation and doubtful debts. No provision was made as to the excess profits taxes because the company desired to await the terms of the pending revenue bill.

The Goodrich Company report for 1917 showed profits of $12,794,677 before making war tax allowances. After charging off $2,250,000 for such taxes there remained a balance for dividends of $10,544,677.

Gisholt Turret Lathe Adaptable To Many Uses

An examination of the Gisholt Turret Lathe by prospective users frequently leads to the conclusion that the lathe will fill the particular requirements of service under consideration.

The Gisholt Machine Company has issued a new catalog, which not only describes the Turret Lathe but more particularly what the lathe can do. Purchasers of lathes will be interested in the new catalog.

Precision Instrument Company Has Developed an Air Speed Indicator

At the request of the Bureau of Aircraft Production, the Precision Instrument Company of Detroit has developed an air speed indicator, which, unlike other gauges, is so constructed as to have all parts interchangeable, making replacements easy.

The gauge is a Venturi design of the Lahm type. The pressure side of the gauge is connected to the diaphragm, the vacuum being within the case.

The Precision gauge is accurate within 1½ miles over the entire scale; the friction does not affect the reading one mile per hour; the pointer remains steady under test conditions, and error due to tipping amounts to less than a mile per hour.

The Magnet Meter

Herman A. Holz, of New York City, manufacturer of measuring instruments for magnetic and metallurgical testing work, has brought out a standardized instrument for measuring the flux and retentivity of permanent magnets. The device is particularly adapted for laboratory measurements of horse shoe magnets for magnetos. A measuring instrument for this purpose must be capable of measuring not only the initial flux, but its power to retain flux under the adverse conditions of use, particularly those encountered in the case of magnetos mounted on aeroplanes and automobile motors.

The device is so designed that the accuracy of the measurements are in no way impaired by residual magnetic effects, even though a very weak magnet is measured immediately after measuring a strong one.

The instrument is rapid working, rugged and reliable. The current in the moving coil circuit is supplied from a dry cell, and the current in the solenoid circuit from a 6 to 8 volt storage battery. No bushings are required to adjust the instrument for testing different sizes of magnets.

This instrument should be a useful piece of equipment for the magneto designing engineer.

Recent Trade Mark Decisions

The patent office has confirmed through the Court of Appeals several important trade mark decisions. The use of the alphabet is limited to designating origin or ownership, and is not extended to manufacturers to designate gradings and quality of articles.

Another case of conflicting trade marks was decided in favor of the manufacturer who had first registered his trade mark, although it was made popular and became known through the publicity of the second manufacturer. First-come-First-served rule applies, regardless of the circumstances.

Dearborn Chemical Company Has Rust Preventor

A problem which has concerned the parts manufacturer and sub-contractor is the shipment of his products in such a manner that they will reach its destination in presentable condition without any rusting.

Realizing that the development of a material which can be applied on iron and steel products just prior to shipment which will prevent rusting would be of great value in all industries, the Dearborn Chemical Company have, after several years of research, placed their product—No-Ox-Ide—on the market.

This material prevents rust in two ways: first, by forming a physical film against the elements in the atmosphere; and second, by acting chemically on the corrosive elements, thereby preventing them from attacking the metal.

Another product recently put on the market by the Dearborn Chemical Company is Dearborline, which is used to remove the oils, gummy substances, grit, iron filings, and other matter on iron and steel products, leaving the article clear for shipping or the application of paint, varnish, plating or other coating.

Great Lakes Aviation School Remains Intact

Chicago, January 26.—Announcement has been made that the Great Lakes Aviation Training School will be kept intact and that other aviation schools in the United States will be brought to Great Lakes and concentrated in one big school.

Among the schools to be transferred to Great Lakes are: Naval Air Training Station, Pensacola; Boston School of Technology; Navy Liberty Motor School, Detroit; Navy Gas Engine School, Columbia University, New York; Naval Detachment, at Dunwoodie Institute, Minneapolis; Naval Training Station, Hampton Roads, Va.

Book Reviews

HEROES OF AVIATION; compiled by La Tourette Driggs. The author describes the thrilling deeds of aviators in the great war, whose deeds will never die. The value of the fourth arm of the military service is strongly brought out; it seems to overshadow the older branches—infantry, cavalry, artillery—with its brilliant tales of heroism and courageous initiative. This book belongs in every library which is to have a complete record of the war.

This book can be purchased at the Aeronautic Library, Inc., 299 Madison Avenue, New York City. Price $1.65, post paid.

New Aerial Mail Terminal Approved

Newark, N. J.—Three examining officers representing the aerial mail service approved the purchase of a tract as a terminal for the New York-Chicago and other mail routes. The land is known as the Heller Tract.

Mr. T. H. Wheeless, representing the Post Office Department in Newark, stated that the Post Office officials who examined the tract were James B. Corridon, Chief of the Railway Mail Adjustment Bureau; Lieut. James Edgerton, of Nutley, N. J., Chief of Operations of the Aerial Mail Service, and Dr. J. K. Bussler.

Fast Passenger, Freight, and Mail Service Between U. S. and Brazil Is Urged

The American Chamber of Commerce for Brazil has adopted resolutions urging immediate establishment of a fast passenger, mail and freight service between Brazil and the United States under American ownership. The service would be apportioned as follows:

Tri-monthly to Rio Janeiro, Bahia and Santos.
Bi-monthly to Para and Pernambuco.
Monthly to Parana and Rio Grande.

The resolutions are understood to have official support. In part they read:

"We believe it is most imperative for the establishment and maintenance of American trade prestige in Brazil that such a service should be immediately established under American ownership and registry.

"The United States has assumed the role of protector and benefactor of South America, yet has neglected to furnish practical means for promoting trade and friendship. Brazil, who is her best friend and staunchest ally, is dependent upon European transportation companies, which allot only sufficient tonnage to attend to the portion of American trade which cannot be diverted to their own countries.

"By their control of Brazilian transportation, Europeans in the past have profited from freight and insurance exchange by financing trade between Brazil and America. They have also been enabled to monopolize the sale of low grade materials which are profitable only when freights are low.

"We also believe official announcement of regular sailing schedules would be worth millions to American trade, which could contract for business that is now returning to European sources of supply because American firms are unable to guarantee shipments on definite dates. Such an announcement also would enable Brazilian exporters to contract with American consumers for fixed quantities and regular deliveries, enabling the exporters to arrange credits and form organizations for producing and developing products required by America.

"Furthermore, the time to establish this service is now. Government and private interests should make every effort, even at the expense of other plans, to promote Brazilian-American trade relations. because all activities—commercial, financial and even political—depend upon establishment of communications between countries."

The use of aircraft for the completion of this program has been suggested by members of the Chamber of Commerce, an aerial mail company being organized to handle mail between London and Buenos Ayres.

Navy Has Taken Official Films

Naval Air Station, Pauillac, France.—Following the photographing (both motion and still) of the President's convoy, led by U.S.S. *Pennsylvania*, New York to Brest, the overseas section of the Photographic Division of the Bureau of Navigation, U. S. Navy, in charge of Lieut. Wells Hawks, U.S.N.R.F., left the air base supply station, Pauillac (Gironde), France, December 29, 1918, on a trip to take in all of the Navy activities in European waters. The party has just completed a week of photography in this vicinity and station, which is in command of Captain F. T. Evans, U.S.N., and from which station all of the planes and supplies for flying in France have been assembled and distributed. The party in association with Lieut. C. E. Ruttan, U.S.N.R.F., the aviator and photographer, made a series of midair photographs with two great seaplanes or flying boats. The aircraft went up to a height of 2,000 feet and photographs, both motion and still, were taken of each machine as it darted under and over each other above the river. In one machine, with Ensign Lopp, pilot, was Lieut. Hawks, while in the gun pit forward Chief Yeoman Harold Wenstrom ground out film from a motion picture camera. In the other machine was Lieut. Ruttan with an aerial camera, Chief Yeoman Edgar Hopp with a graflex, the pilot being Ensign Talbot. Lieut. Ruttan had just come from Brest, where in a dirigible he made pictures of the President's ship, while Lieut. Hawks' party worked from the forward turret of the battleship *Pennsylvania*. Pictures were also taken of the convoy by Chief Printer J. J. McCutcheon, who has been in charge of the photographic hut at the Pauillac station. For the tour the party travelled in a big truck fitted for apparatus and all supplies, rations for out of the way journeys. The party left here for Brest, a run of 458 miles, stops being made at Bordeaux, LaRochelle, Rochfort and the mine sweeper base at Lorient. After Brest the party headed for Paris, after picturing the Marine Camp at Finistere. From Paris it will go to Chateau Thierry and then cover places wherever the Navy had activities, covering the ground traversed by the big 16-inch battery, which the Navy sent into the interior on railroad cars. The activities in England will be covered in a like manner.

Aeroplanes May Protect Our Forests

The forest service of the United States Department of Agriculture is desirous of installing an aeroplane patrol service in connection with its work of fire protection, but is unable to put the plan into effect because of an insufficient appropriation. This information became known through a letter written to the Standard Aircraft Corporation of New Jersey by John L. Hall, Acting Forester.

"We have given considerable thought to the use of aircraft in the fire patrol of the national forests," declared Hall. "I believe that they could be used to excellent advantage and would like very much the opportunity of giving them a thorough trial. The Forest Service, however, as a government agency, is not prepared to purchase and operate a sufficient number of aircraft to adequately patrol the national forests; our appropriations are entirely too limited for a project of that magnitude.

"Similarly we are hardly in a position to ask Congress for additional funds for this purpose in view of the equipment now on hand by the Division of Military Aeronautics and also the fact that this division has numerous trained officers, observers, mechanics, etc. Briefly, we should like to have the Division of Military Aeronautics cooperate with the Forest Service in the patrol of national forests through the use of aircraft."

It is expected that the Forestry Bureau will urge Congress to provide an arrangement whereby the surplus of government aeroplanes on hand may be utilized for the important duties of forest patrol. The advantage of aerial scouting over the present methods has been forcibly impressed upon the forestry officials. A plan of operation similar to the one used in connection with the air-mail service is contemplated.

It has been estimated that thousands of dollars worth of valuable timber would be saved annually if flying machines were used for the detection of forest fires and the transportation of fire-fighting crews to the scenes of conflagration.

Weather Bureau to Use Aircraft

The Weather Bureau is contemplating the utilization of aeroplanes. C. F. Marvin, Chief of the Weather Bureau, made this statement in Washington recently:

"Unquestionably meteorological observations in aeroplanes will eventually form an important feature of the Weather Bureau work. There is no reason to doubt that such observations, taken at short intervals of time and over widely distributed areas, would materially assist us in determining the depth, extent and intensity of storms, and therefore, in increasing the accuracy of the weather forecasts."

Dirigible C-3 on 5 Day Endurance Test

Cape May, February 1.—The 300 foot dirigible C-3 of the submarine patrol station at Sewell's Point, manned by eight men, with supplies and provisions for 120 hours, started on January 30 for a five day endurance flight. So far she has not flown more than thirty miles from Cape May Station, but has hovered over the Army Hospital, exchanging signals with the wounded men and the nurses stationed here.

The dirigible is in command of Ensign Houghton. The men will receive a prize of $8,000 each if they succeed in completing the test.

Seeks Permission to Erect Hydroaeroplane Hangars in New York Harbor

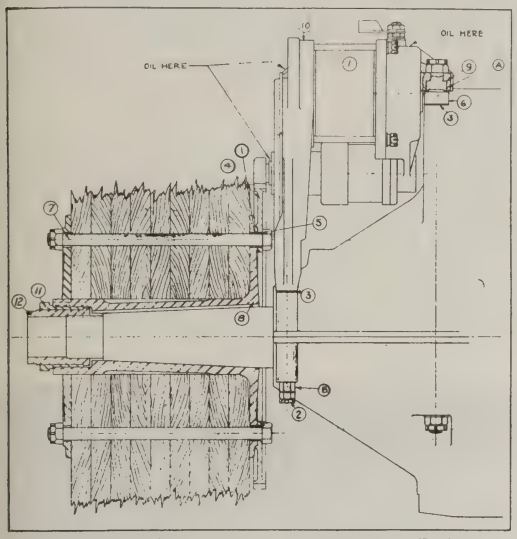
New York, February 3.—An official proposal for the construction of ten hangars has been received by Commissioner of Docks, Mr. Murray Hulbert, to serve as the New York terminal for aerial service between New York, Boston and Philadelphia. Mr. Hulbert will approve the proposal, with the recommendation that the hangar be erected where they will not interfere with the heavy traffic in New York harbor.

Trancontinental Flight Cost $2 Per Mile for Eight Men

Washington, February 3.—Major Albert D. Smith started on the return flight to the Pacific coast from Bolling Field.

The trip from Rockwell Field, San Diego, to New York was accomplished in a flying time of fifty-five hours, for a distance of 4,500 miles. The total cost of the pioneer flight is given as $8,827.50 for the four planes and eight men.

The return journey will cover the southern route, the eastward trip having been made over the northern part of the country.

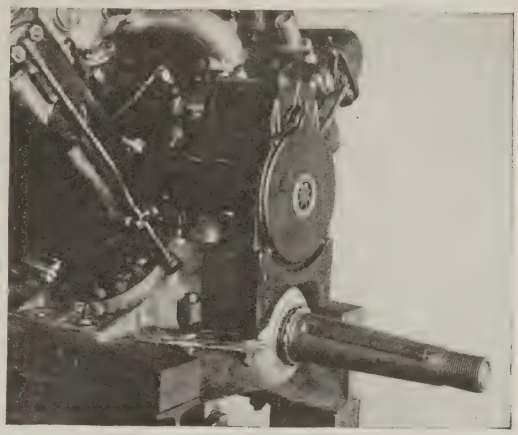


Oversea Aviators Plan Reunions

Aviation Instruction Center, France.—Pending demobilization of America's largest oversea instruction center, plans are under way at this post to make chance meetings of soldiers attached to the Aviation Instruction Center possible. A fraternal organization bearing the name "Issoudun," having as its emblem the Skull and Cross Bones, is to form the basis of reunion. It is proposed to have enterprising hotel men designate a room in their hostelries as "Issoudun" room, and to maintain registers of local "Issoudunites." As practically every aviator who has served in France has at some time or other been assigned to this post, the possibilities of such a mutually helpful and fraternal organization are bright. A plea for activity on the part of those already in the United States has been issued.

THE BIJUR ELECTRIC STARTER FOR AERO ENGINES

AMONG the war-time developments in the aeronautic field of which nothing has hitherto been published are the electric starters built by the Bijur Motor Appliance Company for the Liberty and other aeronautical engines, and supplied in some quantity to the Navy. Until recently there has been a federal injunction in force, prohibiting the disclosure of this device without permission of the Secretary of War, or of the Navy, but this has lately been vacated.



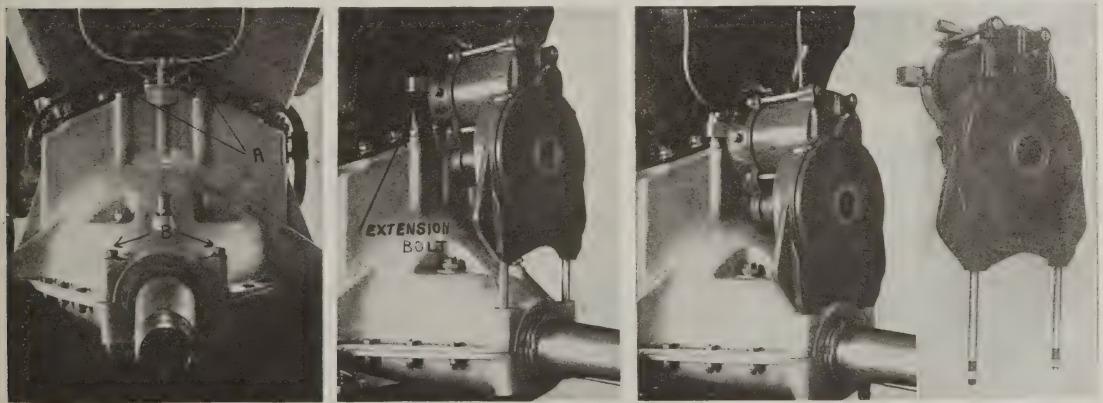
As will be noted from the accompanying illustrations, this device embodies several interesting features. The mechanism consists of a relatively small electric motor, of special design, fitted with a double gear reduction and a special form of the Bijur automatic shift. This mounts directly on the crankcase at the propeller end of the production Liberty engine, without the use of intermediate brackets and without making necessary any alteration to the engine.

Application of the Bijur Starter to the Liberty Engine

To mount the Bijur starter on the Liberty engine two nuts at the base of the cylinders nearest the propeller end (marked A in illustration) are removed and special extension studs are screwed on. Two lugs on the starting motor casing fit over these and are retained by the original engine nuts, which are put on the extension studs. The two end bearing bolts at the extreme propeller end of the engine crankcase (marked B in illustration) are removed and are replaced by two long studs which project from the starter housing.

Normally there is no connection between the starting motor

The Bijur Starter on a Hispano-Suiza Engine



and the crankshaft. A gear ring is placed inside the propeller hub flange and held by the regular propeller bolts passing through holes jig-drilled for the pupose. The pinion of the starting motor is normally retained within the housing. When the starting switch is depressed the pinion meshes with the teeth of the gear ring and cranks the engine. The starting of the engine under its own power automatically demeshes the pinion. Provision is made which eliminates the possibility of the teeth jamming and they will not mesh with the gear ring if the switch is depressed while the engine is running. The use of an eight-tooth pinion is something of an innovation and makes possible a high gear reduction.

The Bijur Liberty Starter was originally designed for the Navy for use especially on seaplanes. At the suggestion of the Airplane Engineering Department of the Signal Corps, the design was made such as to obtain a starter of minimum weight and current consumption combined with a maximum of cranking power. It was thought that the obtaining of these two objects would, of necessity, entail the cutting down the cranking speed to a very low value, but this was found not to be the case. The success of the design as produced will be evident from the following data:

Weight of starting motor..... 20.5 lbs.
Normal cranking current.....100 Amperes (12 volt battery)
Maximum torque available on engine crankshaft..1300 ft. lbs.
Normal cranking speed (crankshaft).....40-50 R.P.M.

The propeller end of the engine was selected as the most feasible place of application because it makes possible the use of a simple and sturdy form of drive without the use of clutches or couplings. It also makes use of space not available for other purposes, while it is often desired to drive auxiliaries from the ignition end of this engine.

Present practice also seems to tend to the use of a fire bulkhead closely behind the ignition end and gasoline tanks immediately beyond, which makes this end of the engine more or less inaccessible. The Bijur Company states, however, that it is prepared to furnish similar starting motors to fit the ignition end of this and other aeronautical engines.

The Bijur Electric Starter applied to the Liberty "12" Engine. 1—Engine without starter. 2—Application ready for starter; starting motor in position. 3—Application complete. 4—The entire starting motor assembly

THE KING-BUGATTI AVIATION ENGINE

By G. DOUGLAS WARDROP, M.S.A.E., A.S.M.E.

WE are enabled to present to the readers of AERIAL AGE this week the first comprehensive engineering description of the King-Bugatti Aviation Engine, constructed by the Duesenberg Motors Corporation of Elizabeth, New Jersey, for the United States Government. Because of its unique type of design the Bugatti, when it was first brought over from France, and it was determined to put it into manufacture in this country, aroused a very great deal of interest in automotive circles, the interest being second only that evidenced in the Liberty. The Bugatti was of the geared type possessing certain features not embodied in the Liberty, and with the special feature of being able to mount a 37 millimeter cannon firing through the propeller shaft.

The United States Government put the redesigning of this power plant in the hands of Charles B. King, A.M.E., of the Signal Corps and he was made responsible for all changes. With a large force of draftsmen the work of adjusting the Bugatti type of design to American manufacturing methods was undertaken and upon the completion of the redesigned motor Mr. King transferred to the Aircraft Production Board a report which considered carefully all the details which are discussed hereafter and in which only minor changes have been made, since the report was handed in, which emphasizes the good judgment used when the motor was being redesigned.

The test referred to was one of fifty hours' endurance, ten periods of five hours each, the first half hour at 410 horse power and 4 hrs. 30 minutes at 380 h.p. The test was made at the Duesenberg test room. The compression ratio of the motor was 5-1; the gear reduction 28:42. The carburetors used were four special Miller with barrel throttle, with choke 1⅞", and 7 jets size No. 76, 76, 75, 72, 69, 58, 53. Four Dixie Model 800-38° advance magnetos; AC Titan Spark Plugs, two per cylinder. A calibrated propeller was used, and power readings used corresponding to speed reading. During the test a grand total of 19,284 H.P. hours were delivered.

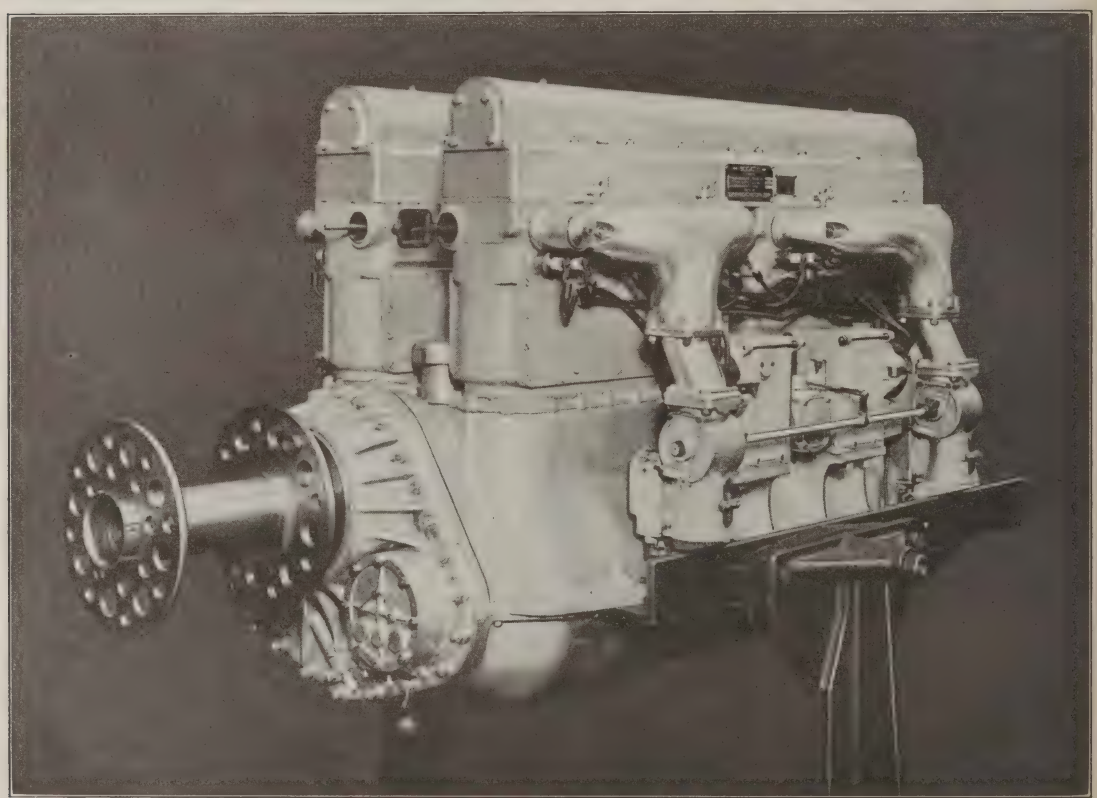
Previous to this test 9 engines had been assembled and had run a total of 110 hours, during which test many details were studied. One of the points that required special study was the pressure oiling system due to cross interference of oil in the crank case. The non-pressure system as used in the French type of Bugatti was considered unsafe owing to the many long leads and on the uncertainty of outside temperature, and it was consequently abandoned. The pressure system developed by Mr. King has worked out very satisfactorily, as was proved by the fine condition of the bearings and running parts after the fifty hour test.

During the fifty hour test the performance was very consistent, as will be noted from the charts and tables printed herewith. The condition of the spark plugs, valves and cylinders, showed that the water circulation was satisfactory in every way. No valves required to be ground during the test and they were found to be in good condition when dissembled. From their appearance it is believed they would have stood an additional fifty hours.

In order to fully demonstrate and test the design of the reduction gears and bearings a propeller with extreme pitch for tractive effort was used throughout the test. It had a pitch of ten feet and was 9 ft. 4" in diameter. Owing to the high velocity of the wind passing over the engine during the test the forward carburetors worked under different conditions than the rear ones. All four carburetors were calibrated in the jets before the test, but the forward carburetors showed a different color of flame at the stacks, the rear caburetors being somewhat obstructed as to air currents by the magnetos directly next to them. Suction elbows were not used, the air being taken into the venturi passages. This probably accounts for the consumption of gasolene, which was .583 pounds per H.P. hour.

After the test all the pistons and piston fins were calipered and found round and true.

Upon dissembling the two forward cylinders adjacent to the propeller were found cracked above the flange in the skirt, but this did not interfere with the running. It was not discovered until after the engine had been taken down. This accident was accounted for by the fact that the iron of the cylinders was not in accord with Signal Corps specifications. The discrepancy of material was immediately remedied.



The test of fifty hours thoroughly demonstrated the reliability of the engine and endorsed all the changes that were made in the French design. The H.P. in the American motor was found to be greater than that of the French.

American and French Bugattis Compared

In the course of a very interesting report Mr. King offers definite data concerning the specific changes made in the Bugatti design and the reason therefor. Owing to the fact that the French engine which was sent over to this country had had a limited test in Paris of 37 hours and had not been in flight, all of the points in the design were very carefully considered. It was soon discovered that if the job was to be made a production one numerous changes would have to be made. Some of the more important of these changes are presented in diagram.

Water Jackets

It was evident that difficulties were experienced in cooling the valve seats of the French Bugatti, as cylinders and sample sections of used cylinders (see Illustration K) showed cracks between the exhaust and the inlets at Point A. See also Fig. 16 showing on the plant the point of fracture. In the American design, centers of the valves were increased in both directions from center of line, namely, from 1.732" to 1.764" and also from 1.693" to 1.694". This is clearly shown on Fig. 16. Section AA, Fig. 20, shows the deep unjacketed section of the cylinder in which the strain was set up, causing the cracked valve seats. To obviate this difficulty, the shape of the intake passage and exhaust passages were improved and the distance BV, showing the height of the unjacketed wall (see

The sixteen cylinder King-Bugatti aviation engine

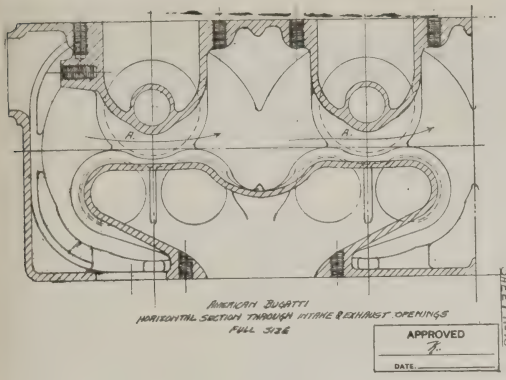


Fig. 15

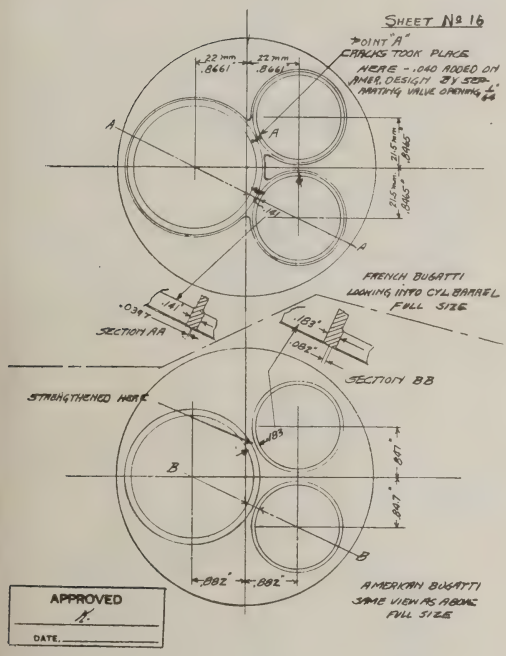

Fig. 16

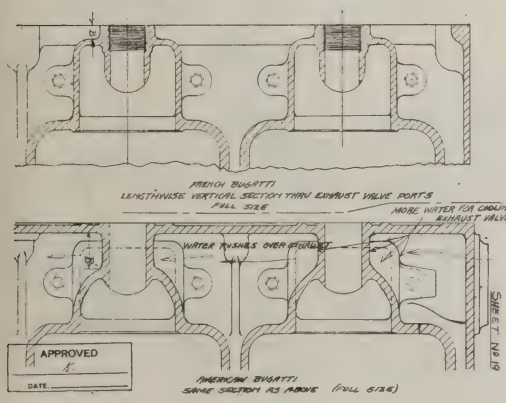

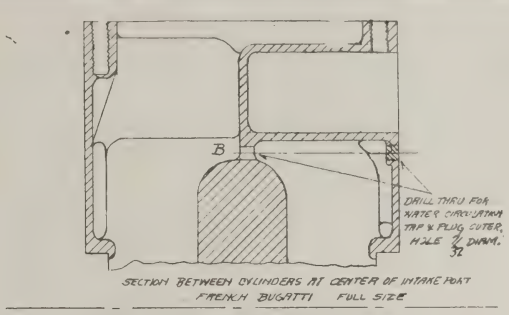

Fig. 19

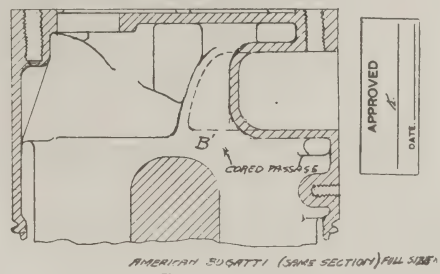

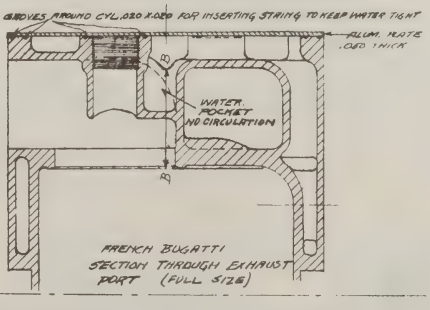

Fig. 17

SHEET No 18

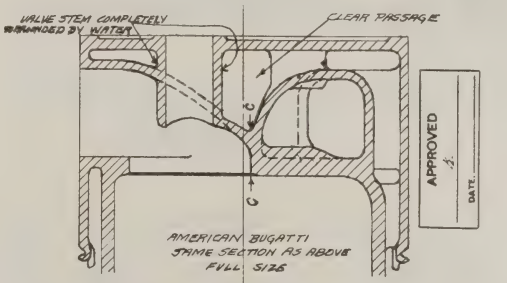

Fig. 18

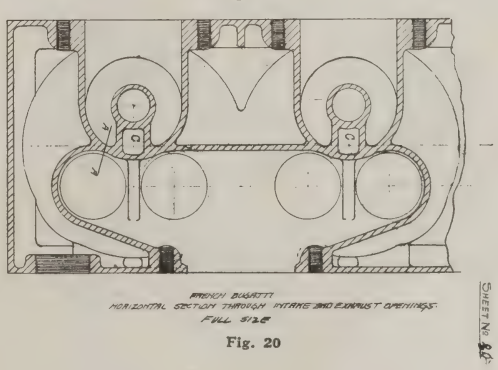

Fig. 20

Fig. 18) was reduced to distance CC, and at the same time circulation water was swept through this formerly restricted passage. To further improve the water circulation around the valve seats the small drilled hole B (see Fig. 17 and 21) was changed to a larger cored passage B', shown on this same Figure. The dead pocket C (see Fig. 20) was entirely eliminated and in its place clear passage was made as at D (see Fig. 15). The exhaust valve stems were not properly taken care of as to heat transference to the water jacket. The depth of water around valve stem guides is shown on Fig. 19, where the French Bugatti and American Bugatti are contrasted. (See B and B'.) Owing to poor conductivity through threaded portions of valve guides, the threading was eliminated and cast iron valve guides were pressed into place, thus making a much more uniformly cooled stem. The bronze guides taken from the French Bugatti showed evidence of high heat.

Propeller Gears

In transferring the French pitch of 5.6 to American pitch, it was considered that the coarser pitch, namely 5, would be preferable (see Fig. 32), and the number of teeth was changed but the ratio was practically maintained. It was further determined that there was an error of 4°10' in the French Bugatti engine between the timing of the right and the left crankshafts. As this would have considerable effect in the cross firing from the magnetos and, further, the engine would not be perfectly timed, this was corrected by changing belts from eight to nine in each gear. This with a certain relation between the holes and the teeth, enables the engine to be timed as stated with a slight error of 20'. The difference in running between engines thus timed can be easily appreciated.

Propeller Shaft and Bearings

At the request of Capt. Lepere the propeller was moved forward 3¾" to assist in stream lining the plane. This dimension would have brought an overhang of 8¾" forward of the front supporting bearing in the French engine. (See Figs. 23, 23A and 23B.) This was far from good practice and was not contemplated. A deep groove radial bearing was selected and the comparative overhang was reduced from 8¾" to 3" and further the gear load was taken between two such bearings. This deep groove bearing has proven in American practice to be good, as it takes both radial and thrust loads. The overhang gear as in the French engine has not been found successful in practice, as a certain wedging action takes place from the gear load and forces the true pitch contact line to assume a diagonal line. The ball bearing thrust as used in the French engine permits the balls to be thrown outward by centrifugal force and causes an improper contact on ball surfaces; this can be further aggravated by the wedging action of the gears. In the parts removed from the broken up French engine (see Illus. M) the thrust rings and balls were burned to a deep blue. The assembly of the propeller shaft bearings is a difficult "in place" assembly in the French engine. In the American design the bearings are entirely an "outside" assembly. The sliding door in front cover of the French engine has been eliminated.

Water Pump

The French Bugatti pump as mounted on the engine permits water leakage to enter the sump and mix with the lubricating oil. This will lead to difficulties in the operation of the engine. (See Fig. 22.) In the American model the pump was moved back, a better support added (see distances C and C') and an opening was arranged so that the leakage could pass outside of engine sump. Two bearings were provided on pump shaft. The rotor is riveted to shaft and driven with a Woodruff key. Lubrication is provided with water which passes through center of shaft. It is found in practice in draining the system in cold weather that where the rotor is brought clear to the housing wall (see Dimen-

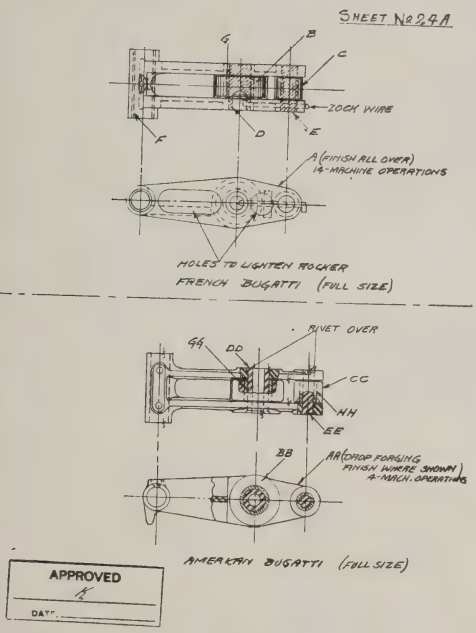

Fig. 24A

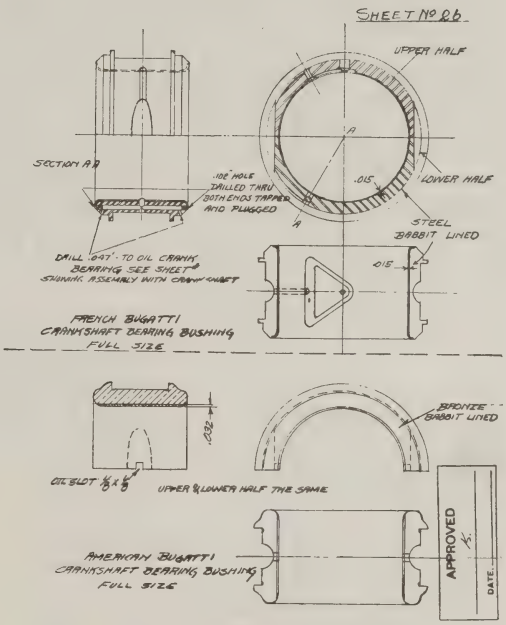

Fig. 26

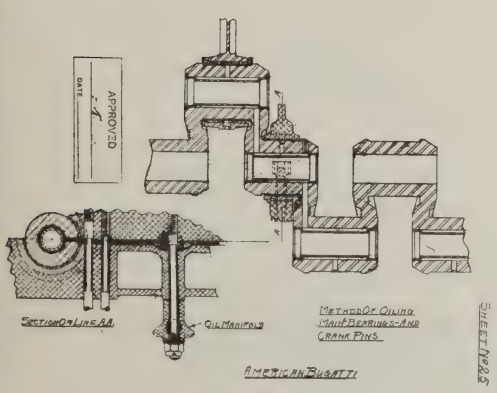

Fig. 25

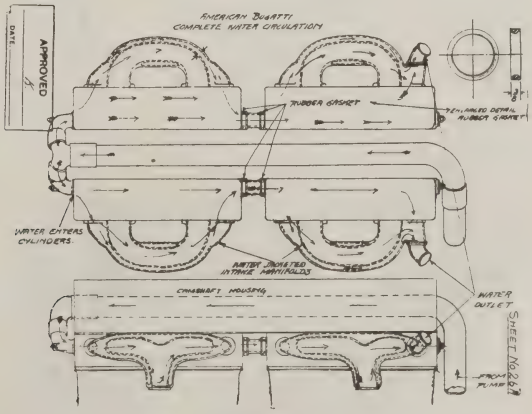

Fig. 26A

sion A) that water is held by capillary attraction in this narrow space and freezing results at this point and when the engine is started the pump shaft is sheared off. This space has been opened up in the American model (see Dimension A') and the water is thus permitted to freely pass out. An elbow has been added to pump cover which can be assembled pointing in any desired direction. It is believed in this redesign that the troubles experienced during the official test have been eliminated.

Rocker Arms

These are shown in detail on Fig. 24. Simplicity of machining was studied and from 14 machining operations on the French Bugatti this has been reduced to 4 on the American model. Each engine has 48 rocker arms; therefore the French engine has 672 machine operations as against 198 on the American model.

Piston and Piston Pin

The five piston rings, namely, 3/32 of an inch face are not considered commercial and were replaced by three rings ⅛ of an inch face. (See Fig. 31.) Further, the effective length of the piston was increased from 4 1/16 to 4⅞ and said piston was made of the slipper face principle, which eliminated contact with the side walls and gives better air cooling on the hot unjacketed vertical sections between cylinders. Ribs have been eliminated and the pistol wall arranged for uniform heat transference to the jacket. The stresses on the piston ring were figured and found to be high, indicating a weakness. The diameter of pins was therefore increased from 63/64 to 1 1/16". No report of breakage pins was received with engine, and upon receipt of the copy of the French Official Test received in May, 1918, from Lt. Col. Dunwoodie of the Technical Section, it was noted that in the test run of November 16, 1917, that piston pins were broken and three had to be replaced.

Water Circulation

The French engine had a water pipe with hose connections, three to each cylinder block between the cylinders. This is a difficult assembly, and in case of a leak in a complete engine means the removal of the exhaust pipes (see Fig. 25). In the American design the water can be sent through either end at the top of the cylinder blocks, thus sweeping all steam from exhaust seats. Part of it is deflected through the inlet manifolds. (See Fig. 26.)

Cam Shaft Gear Mounting

In the American model a loose piece is avoided, at center of shaft; also the small internal grinding in the camshaft. (See Fig. 26.)

Vertical Shaft Arrangement

In the French engine gear Y' (see Figs. 30 and 35) was screwed on the end of shaft Z'. This at once prevented interchangeability, as it in no way determined the location of a tooth in relation to the crank pin. This in each individual French engine was to be corrected by proper timing and then drilling the hole for pin N in vertical shaft. This was avoided in the American model by extending key to crank cheek ZZ fitting the gear directly to this same shaft. The key was accurately cut in relation to a tooth and uniform timing was at once obtained. The vertical shaft drive above was taken through two square shaft ends and not through a pin.

Connecting Rod Ends and Liners

The French Bugatti engine had no liners in connecting rod ends (see Fig. 24) and depended on a thickness of babbitt of .014 in. directly on the steel shell. This being an extremely thin layer, a considerable risk was offered in a 16 cylinder engine. In case a rod was burned out steel would come in contact with steel, resulting in a seizure of rod on crank pin, a broken rod would follow, meaning the ultimate wreck of engine. In the American engine, bronze liners were put into rod ends and .047 inches of babbitt was used. In case of a burned out rod, steel will come in contact with the bronze and the liner therefore will not seize on the crank pin. This will enable the flier to still operate his engine and make a landing. Owing to the oil pressure in the American engine, the long grooves in bearings are eliminated and in their place the short grooves are used. The replacing of liners in rods is comparatively easy and does not demand a quantity of spare connecting rods for repairs.

Main Bearing Liners

These are of bronze and not of steel as in the French engine, and for the same reason as in the connecting rods, viz., that a burned out bearing will not seize the crankshaft. Attention is called to the small lubricating oil holes in the French liners. These take care of the pins and are of such dimensions .047" (see Fig. 26) that they can be easily clogged, whether with sediment or cold oil. This is an open system with low oil pressures, and hence these passages cannot readily clean themselves. It is possible that clogging of these holes in the French engine caused the wreck of this engine on the test stand.

Carburetors

The placing of the carburetor float chambers in the French Bugatti is not according to standard practice and in climbing or in a nose dive a different mixture is likely to result in the forward and rear cylinders. (See Figs. 33 and 34.) In the French engine one float chamber is forward of the jet and one is in the rear. In the American engine they are both brought to the rear. The American engine therefore gets a uniform mixture in all cylinders.

Ignition

It was decided that two magnetos would be used. With the Splitdorf magneto a separate distributor is used mounted on the ends of the camshafts. The Simms magneto was used for half of the production, and these two magnetos were each equipped with their own distributors. A saving of over forty pounds was effected by this arrangement as against the use of four magnetos. Each engine is completely cross wired to each magneto; in other words, it is perfectly synchronized, and is such that each magneto taken separately will operate engine, and owing to this perfect synchronization the two magneto arrangement runs with less vibration than the four magneto scheme. With the two magnetos and the distributor a starting magneto is supplied. This consists of a hand operated independent magneto in the fuselage, which delivers a shower of sparks on the proper cylinder as selected by the distributor. Ease of starting is facilitated in this manner.

Oiling System

The oiling system as applied to the French Bugatti engine can be considered an open system non-pressure type, the pressure being determined by the diameters of the open orifices. (See Figs. 37 and 38.) In other words, with heavy or cold oil, the oil will take the path of least resistance and will not travel to the remote ends of oil leads. The small openings in bearings (as shown on Figs. 26, 37 and 38) become clogged with sediment, waste or coagulated oil. Owing to the pressure not being sufficient to clear these passages, trouble can be expected. Such trouble has already been experienced in engines built in this country. The fundamental principle in the American Bugatti engine was to obtain a true pressure system on all bearings, including camshafts. (See Figs. 39 and 40.) The oil to be controlled by a relief valve (shown on Fig. 39). This can be regulated and the proper pressure obtained. The seat of this valve is scored so that at all times a flow of oil is supplied to the gear faces and an additional flow will also come from the lift of this relief valve from its seat. All exterior oil pipes which are subject to breakage have been eliminated in the American Bugatti engine. The oil is fed upwards through drilled holes in crankcase and directed to the center of the camshaft through two openings. At each revolution of the camshaft a small groove in the bushing of this bearing passes a drilled oil hole lead to the center of camshaft. This squirt of oil is directed outward at each revolution over the cams, gears and rocker arms. The tie-bar in this engine is brought in contact with the front gear cover and the oil is led directly into same without the use of exterior piping. The oil lead to the gauge is further brought out at the rear end of this same member and an extra length of gauge pipe is thus avoided. Two oil pumps are driven by the crankshafts and said pumps are mounted on the propeller gear housing. One pump is arranged

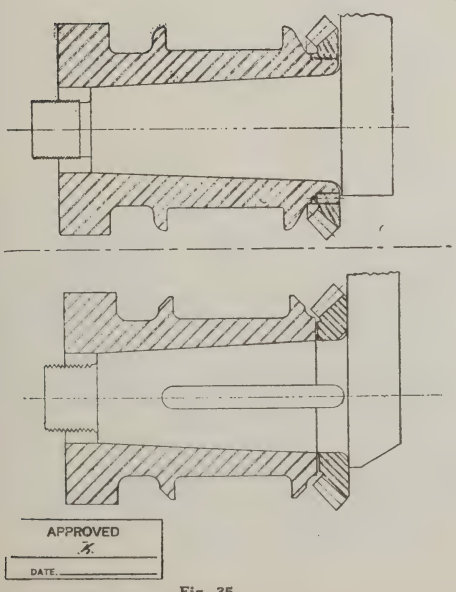

Fig. 35

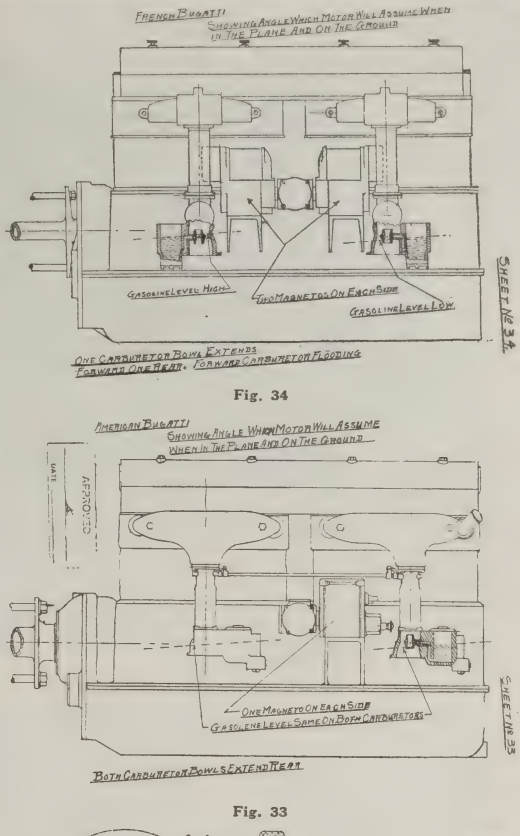

Fig. 34

Fig. 33

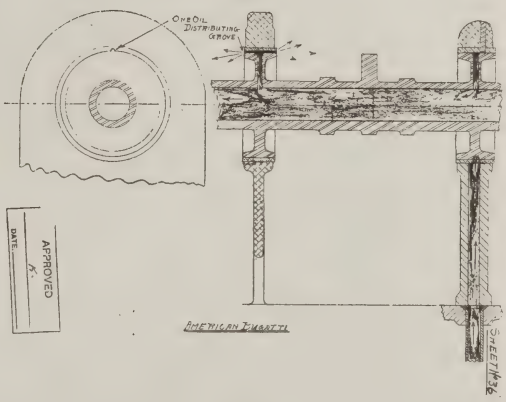

Fig. 36

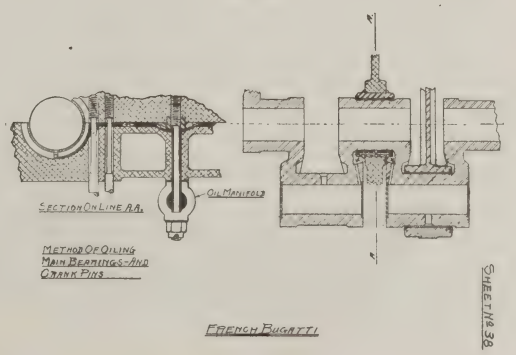

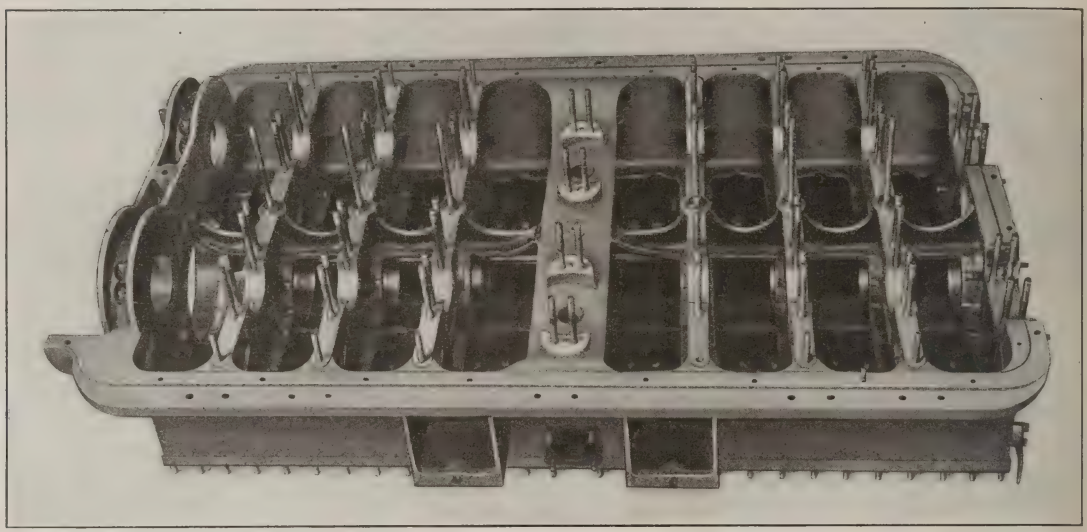

Fig. 38

to supply the pressure system, the duplicate pump is used to clear the forward end of the sump in a nose dive. In climbing, the oil is led out of the crankcase by gravity to the oil supply tank. Pipe into said tank being led into a position at the rear of the tank in order that the oil cannot flow back in the crankcase by gravity.

Outside Water Jackets

It was first contemplated to weld the sheet iron jacket to the cast iron cylinder by the oxyacetylene process. (See Fig. 27.) After certain experiments were carried out, it was considered that this was not a production job and the arrangement as shown on Fig. 27A with aluminum covers will probably be adopted.

This examination by Mr. King and his engineers led them to the conclusion that the Bugatti engine as delivered by the French to the American government was not a commercial engine, as it was necessary to redesign the entire motor and to bring it in line with American practice.

THE MIESSNER AIRFONE

THE Miessner Airfone, designed and developed by B. F. Miessner of the Emil J. Simon Company, builders of radio apparatus, is a device of great value for intercommunication between pilot and student or pilot and observer.

In a recent interview Mr. Miessner expressd the opinion that this device could cut in half the time required for novices to learn to fly. This statement is not based on fancy, but is corroborated by Army Officers who have employed the Miessner device in the instruction of Air Cadets.

As an instance of the assistance which a simple and efficient means of communication between pilot and student may be in accelerating the student's progress, student aviators have been placed in sole charge of the controls for the first time and made ten-mile flights successfully, each error made by the student being instantly corrected by the instructor. This, contrasted with the usual method of taking the controls out of the student's hands, and telling him half an hour later what his mistake was, constitutes a great advance in methods of instruction.

The Airfone is entirely an acoustic instrument, it being a speaking tube so designed as to be adapted to use on an aeroplane in full power flight regardless of the size of its motors. Although telephones for inter-communication on aeroplanes depending on microphonic principles have been the subject of extensive experiments none has been developed which equals the efficiency of the Airfone according to statements of army officers. Furthermore the electric telephone requires expensive cumbersome and sensitive apparatus—a battery or dynamo as a source of power, delicate microphones and wiring subject to breakage. The electrical telephone for intercommunication is only necessary in cases where a wireless telephone transmitter is installed on the aeroplane in order to provide currents to vary with voice characteristics for modulation of the transmitting vacuum tubes.

The chief difficulty encountered in the design of interphones, the name usually applied to devices for intercommunication between passengers and pilots on aircraft, is to make it transmit clearly and loudly sentences uttered without particular effort on the part of the speaker and yet fail to transmit the considerably louder noise of the motor and the whistling of the wind.

It is this problem which has baffled inventors in this field.

Various efforts, however, with true

The Miessner Airfone in position

American persistance have been made to rid the telephone of these undesired sounds and some of these are mentioned below.

1. By provision of a special mouthpiece usually of soft rubber designed to fit around the mouth and nose of the user so as to exclude the extraneous sounds. This is undesirable for several reasons: Poor articulation results from the restricted lip and jaw movements and because the enclosure of the mouth muffles and suppresses the voice vibrations, especially those of the higher frequencies forming the hisses, t's, etc.—and allowing only the main fundamental tones to be transmitted satisfactorily.

2. By using a modified Maxim silencer scheme wherein the sudden pressure impulses of the most powerful noises such as those of the motor exhaust are prevented actuating the transmitted with full intensity by placing a series of small acoustic apertures with associated expansion chambers in the sound path through the mouthpiece to the diaphragm. While this scheme subdues the most powerful of the noises, it cannot differentiate between the voice sounds and the many complex noises attending aircraft flight so that these latter are still quite troublesome.

3. By providing throat and breast transmitters which are actuated by vibrations of the vocal chords transmitted through the neck or chest, and which by being pressed against the body are so covered up or enclosed as to greatly hinder the entrance of outside noises.

While these are successful to a degree in excluding outside noises and in transmitting vocal chord vibrations, the articulation is very poor owing to the almost entire omission of those very necessary modifications and of additions to the vocal chord sounds produced by the tongue, teeth, lips, etc.

All of these telephone methods of communication, therefore, have been beset by these various important obstructions, aside from the less serious difficulties in the way of batteries, delicate electrical mechanisms, connections, etc., all of which are more or less constant source of trouble.

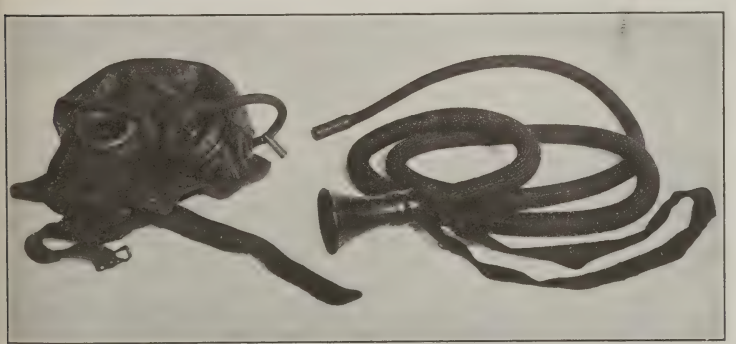
It remained for Mr. Miessner, whose extensive experience as a radio engineer and research expert admirably fitted him for his task, to attack the problem from a new angle, and to design a simple, lightweight and efficient intercommunicating device which transmits speech to the exclusion of interfering and extraneous sounds.

That this has been successfully accomplished by the designer of the Airfone is the opinion of many army officers who have tried out this device. Not only has the Airfone been tested under flying conditions on training planes, but has given entire satisfaction on planes mounting 400 H. P. Liberty Motors while in flight and making loops, nose-dives, tail-spins and other stunts.

Another successful test performed consisted of talking into the transmitter placed only two feet from the cylinder exhausts of a 12-cylinder Liberty Motor mounted on a test stand and in the full propeller slip stream. No difficulty was experienced in making out the entire conversation, despite the severe conditions.

The Airfone is a form of speaking tube designed especially for service between pilot and observer, instructor and student, or any aeroplane occupants during full power flight. It consists essentially of a flexible speaking tube provided with a mouthpiece and a neck band and a helmet to which two earpieces are attached, suitable communications between the speaking tube and the earpieces being provided. For two-way conversation two such headgears and tubes are used.

Its present design is based on a very close and detailed study of aircraft noise conditions and on the application of the information gained by this study along strictly scientific lines in accord with the fundamental principles of acoustics.



The two chief considerations governing the design of a speaking tube for aeroplane service have been found to be:

First: Effectively to prevent the aeroplane noises from reaching the ears directly through or around the earpieces; and

Second: To obtain the highest ratio of intensity of voice sounds to aeroplane noises reaching the ears through the speaking tube; in addition it is necessary that the acoustic characteristics of the tube be such as to permit of good articulation.

Of those two governing conditions, the first is met by the earpiece design, which permits of leading the voice vibrations directly to the ears, and of barring to a

The Miessner Airfone Equipment

THE HANDLEY PAGE TYPE 0-400 BOMBER

BOTH in Great Britain and in the United States, the Handley Page has been the principal machine to be put into quantity production for bombing purposes. The American design is similar to the British, except that Liberty "12" 400 h.p. engines are employed in the former, and the Rolls-Royce or Sunbeam in the latter. The Handley Page machines described and illustrated here were built by the Standard Aero Corporation, Elizabeth, N. J.

Accommodations are made for one pilot and two or three gunners, and an observer who operates the bomb-dropping devices. Their placing is as follows: At the forward end of the fuselage is the gunner who operates a pair of flexible Lewis machine guns. Bowden cables at one side of the cockpit permit the release of bombs. Behind the gunner is the pilot's cockpit from which the gunner's cockpit is reached through an opening in the bulkhead separating the two compartments. The pilot is seated at the right side of the cockpit. Beside him is the observer's seat, hinged so it may be raised so as to permit access. Bomb-releasing controls are placed on the left side of the observer extending to the forward gunner's compartment and running back to the bomb racks located in the fuselage just between the wings.

Forward compartments are reached via a triangular door on the under side of the fuselage.

Aft of the bomb rack compartment, the rear gunners are placed. Two guns are located at the top of the fuselage and a third is arranged to fire through an opening in the under side of the fuselage. One gunner may have charge of all the rear guns, although usually two gunners man them. A platform is situated half way between upper and lower longerons of the fuselage, upon which the gunner stands when operating the upper guns.

General Dimensions

Span, upper plane	100'-0"
Span, lower plane	70'-0"
Chord, both planes	10'-0"
Gap between planes	11'-0"
Length over all	62'-10"
Height over all at overhang cabane	22'-0"
Height over all at center panel	17'-6"
Width, wings folded	31'-0"

Areas	*Square Feet*
Upper plane with ailerons	1018
Ailerons (2) each	172
Lower plane	630

Total	710

Volumes	*Cu. Ft.*
Bomb section, 3'-5¾" x 5'-2 15/16" x 4'-5"	80.6
Rear gunner's platform (upper) 3'-3⅞" x 5'-1⅛" x 4'-2¼"	71.45
Rear gunner's platform (lower) 2'-4" x 5'-1⅛" x 4'-2¼"	54.2
Total volume	206.25

Performances

Height (*Feet*)	Speed (*M.P.H.*)	Time of Climb (*Minutes*)
0	92	0
5,000	90	12
7,000		18
10,000	85	32

Service ceiling 10,000 feet.

Main Planes

Planes are not swept back and have no stagger nor decalage. Beyond the engine nacelles, both upper and lower planes have a dihedral angle of 4 degrees

Wing section employed, R. A. F. No. 6. Angle of lower wing chord to propeller axis, 3 degrees.

Aspect ratio of upper wing, 10; lower wing, 7.

Planes are in nine sections. Upper plane center section 16'-0" wide. Intermediate sections 22'-0" wide; overhang sections 16'-10" wide. Beyond this, the ailerons project for a distance of 3'-2".

Lower plane in four sections; two between fuselage and engine nacelles and two outer sections.

Interplane struts spaced as follows: nacelle struts 8'-0" from center of body; intermediate struts 10'-0" from nacelle struts; outer struts 12'-0" from intermediate struts. Overhang rods anchored 14'-0" from outer struts. Overhang beyond bracing 6'-0", including ailerons.

Ailerons are 20'-7½" long; 3'-9" in chord. Overhang portion 3'-1¼" wide.

The accompanying drawing illustrates the manner in which the main planes are hinged aft of the engine nacelles, permitting the wings to be folded back so as to facilitate housing in a comparatively narrow hangar. In folded position the measurement from leading edge of wing to centerline of fuselage is 15'-6".

For bracing between planes, oval section steel rods are used exclusively. Ends are formed to a solid section which is threaded and fitted with a trunnion barrel and forked terminals.

Fuselage

The fuselage is built up with the usual longerons and cross members. Bracing is with solid wires with swaged or forked ends.

Total length of fuselage, 62'-10¼"; maximum width at the wings, 4'-9", tapering in straight lines to 2'-11" wide at the stern; maximum height, 6'-10". In flying position the top longerons are horizontal to the propeller axes; top longerons 12'-3" above ground.

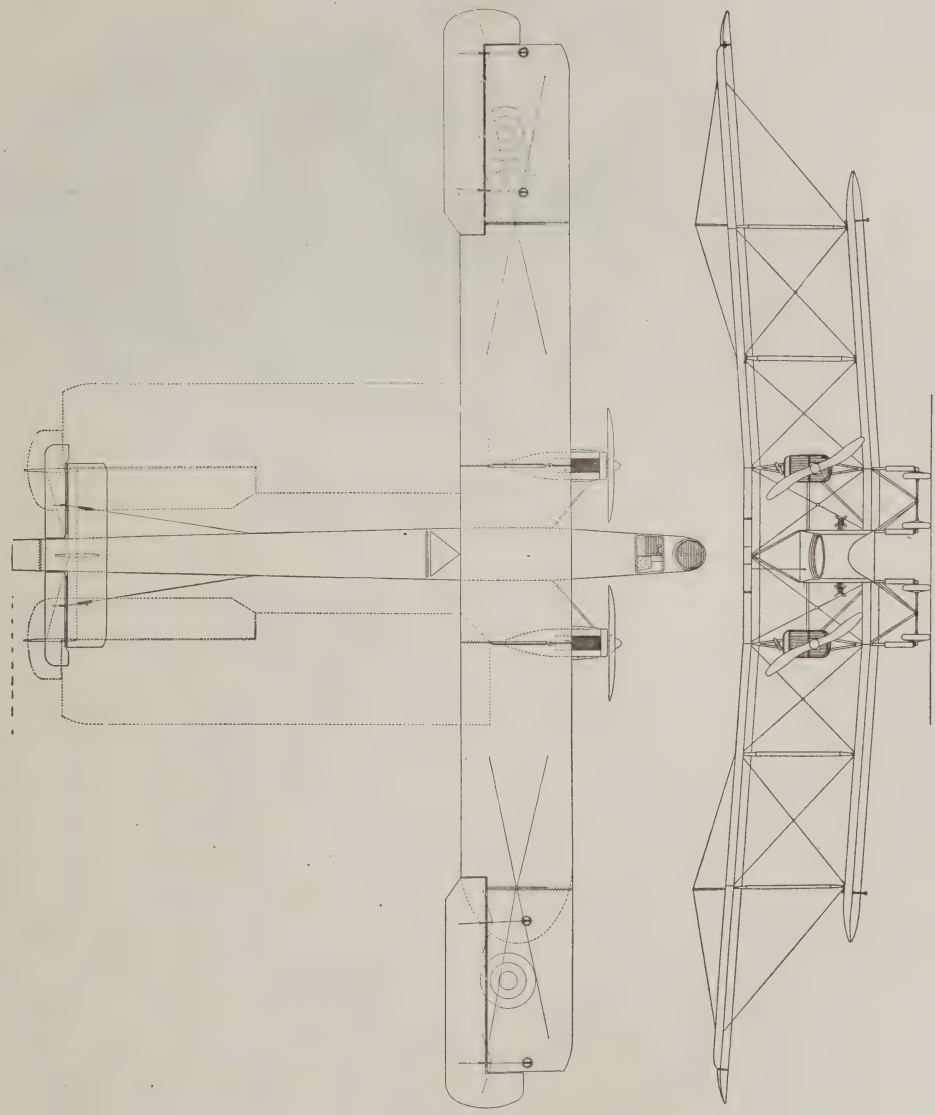
Leading edge of planes 12'-2" aft of fuselage nose.

Tail Group

The tail is of the biplane type with a gap of 6'-0". Average chord, 3'-6 17/32". Chord, above body, 5'-6". Span of stabilizers, 16'-7½".

There are two pairs of elevators 1'-10 15/32" wide and 8'-5½" long.

Struts from body to top tail plane spaced 2'-9¼" from center to center. From these, the outer forward struts and rudders are spaced 6'-3⅞".



Central vertical fin 4'-0" wide.

Rudders are balanced. Width 4'-10½". Con-

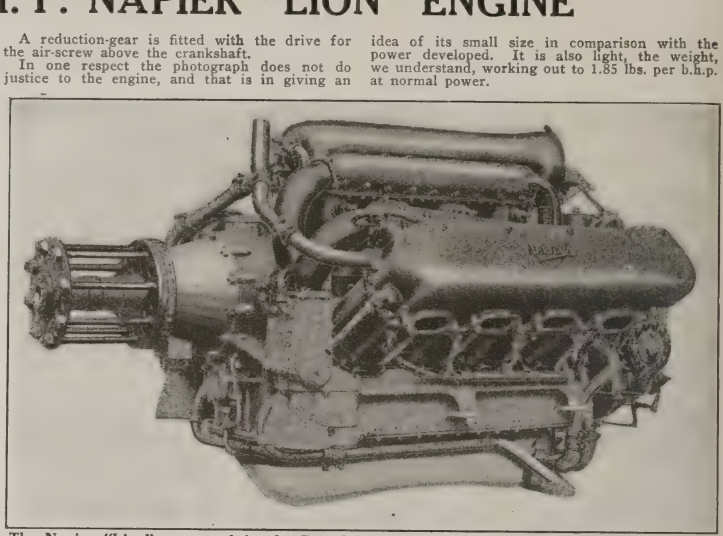
THE 450 H. P. NAPIER "LION" ENGINE

IT is now possible to give a few particulars of the special engine for aero work produced by Messrs. D. Napier & Son, Ltd. The general arrangement of the "Lion" engine can be gathered from the photograph; the twelve cylinders, 5½ in. bore, are arranged in three banks so that three pistons are connected to each crankpin of the four-throw crankshaft, the centre piston having a master connecting rod with links for the side ones. The crankshaft is carried in roller bearings. Made from steel forgings the cylinders are fitted with steel jackets, while the head is of aluminum and carries the camshafts which act directly on the valve heads. There are two inlet and two exhaust valves to each cylinder.



Arranged low down at one end of the engine, the carburetors are fitted with separate intake pipes with a view to eliminating any possibility of the machine catching fire owing to engine trouble. If there should be a back-fire in one cylinder the other two blocks will keep the engine running and suck in the flames. Special attention has been given to the heating of the carburetors, and the water jackets are carried down and round the throttle barrels themselves to prevent them freezing at high altitudes. During a test of one of these engines a temperature as low as 35 degrees Cent. was recorded.

Lubrication has also been the subject of special study; it is entirely automatic and designed with a view to preventing over-lubrication when the machine is dived or climbed steeply for a long time.

All moving parts of the engine are enclosed, and the usual accessories are fitted, provision being made for starting, speedometer drive, etc.

A reduction-gear is fitted with the drive for the air-screw above the crankshaft.

In one respect the photograph does not do justice to the engine, and that is in giving an idea of its small size in comparison with the power developed. It is also light, the weight, we understand, working out to 1.85 lbs. per b.h.p. at normal power.

The Napier "Lion" was used in the British aeroplane that recently established a world's altitude record

CITED FOR BRAVERY

UPON the recommendation of General Pershing, Distinguished Service Medals have been awarded to the following officers for exceptionally meritorious and distinguished service in positions of great responsibility:

Major General Mason M. Patrick, United States Army. For exceptionally meritorious and distinguished services. He displayed much ability and devotion to duty as director of construction and forestry, and, later, as Chief of the Air Service of the American Expeditionary Forces, he perfected and ably administered the organization of this important department.

The commander in chief, in the name of the President, has awarded the distinguished service cross to the following named officers and soldiers for the acts of extraordinary heroism described after their names:

Maj. K. P. Littauer, Air Service, United States Army. For repeated acts of heroism in action near Conflans, France, September 14, 1918, and near Doulcon, France, October 30, 1918. Maj. Littauer volunteered on a mission to protect a photographic plane for another squadron on September 14 and continued toward the objective at Conflans after three other protecting planes had failed to start. In an encounter with five enemy pursuit planes, he completely protected the photographic plane by skillful manoeuvring, although his observer was wounded and his machine seriously damaged. On October 30, Maj. Littauer, on duty as chief of air service of the Third Army Corps, volunteered and made an important reconnaissance of enemy machine gun emplacements at a low altitude near Doulcon. Home address, Alfred Littauer, father, One Hundred and Fifth Street, New York, N. Y.

Second Lieut. James M. Richardson, Air Service (pilot), 1st Aero Squadron. For extraordinary heroism in action near Grandpré, France, October 6, 1918. Lieut. Richardson undertook an infantry contact patrol mission under weather conditions which necessitated flying at an altitude of only 100 meters. Near the front lines machine guns opened an effective fire on his plane and he was wounded in the foot, but he continued on the mission until the front lines of the American troops were located and his observer had written out a report for the division commander. Home address, Miss Emma Richardson, sister, Devalle Bluff, Ark.

First Lieut. John F. Michener, Air Service (pilot), 1st Aero Squadron. For extraordinary heroism in action near Varennes, France, October 4, 1918. Lieut. Michener was assigned the mission of locating the front lines of our troops at a time when dense mist and low clouds compelled him to fly at an altitude of only 100 meters. His observer's signal rockets drew fire from an advanced hostile machine gun battery and Lieut. Michener was wounded in the leg. Despite his wound he continued the mission until the position of our troops was ascertained. He was then compelled to land on shell-torn ground behind the lines, the plane being completely wrecked. Home address, Mrs. A. R. Michener, mother, Erie, Pa.

Capt. John Mitchell, deceased, Air Service, 95th Aero Squadron. For extraordinary heroism in action near Beaumont, France, May 27, 1918. Seeing three enemy planes flying east over Apremont at 2,500 meters, Capt. Mitchell unhesitatingly attacked the three machines, which were in close formation, despite the fact that a fourth, hovering above, threatened to close in and join the enemy formation. He succeeded in shooting down the enemy machine, which proved to be a biplane returning from an important mission. Home address, Walter J. Mitchell, Manchester, Mass.

First Lieut. Asher E. Kelty, deceased, Air Service, 91st Aero Squadron. For extraordinary heroism in action near Crepion, France, September 26, 1918. In the course of a photographic mission Lieut. Kelty, with his observer, was obliged to penetrate a heavy enemy antiaircraft barrage, realizing that obtaining the location of the artillery objectives was of the greatest importance. When a shell struck his machine, his observer was instantly killed and his machine so badly wrecked that it plunged to the earth, thereby causing his death. Next of kin, Mrs. Cora B. Kelty, 1 South Main Street, Rice Lake, Wis.

Second Lieut. Francis B. Lowry, deceased, observer, C. A. C., 91st Aero Squadron. For extraordinary heroism in action near Crepion, France, September 26, 1918. On September 26, while on a very important photographic mission, Lieut. Lowry, with Lieut. Kelty (pilot), realized the importance of the mission and chose to continue their course through a harassing antiaircraft barrage. A shell made a direct hit on the plane, brought it down in fragments, and instantly killed Lieut. Lowry. Next of kin, Walter B. Lowry, 946 Corona Street, Denver, Colo.

First Lieutenant Robert P. Elliott, Air Service, pilot, 96th Aero Squadron. For extraordinary heroism in action near Olizy, France, October 27, 1918. Lieutenant Elliott flew in a formation over the enemy's lines on a bombing expedition. Attacked by a greatly superior number of enemy pursuit planes, his aileron controls soon shot away, Lieutenant Elliott continued to pilot his machine and give protection to his comrades. When his observer was seriously wounded, Lieutenant Elliott left the formation at great risk to himself, and with a disabled machine made a safe landing. Home address, J. M. Elliott, father, First National Bank, Los Angeles, Cal.

First Lieutenant Elmer Pendell, 120th Infantry, Air Service, observer, 168th Aero Squadron. For extraordinary heroism in action November 4, 1918. As observer in D. H. 4 plane. Lieutenant Pendell flew an infantry contact machine over the line of the 7th Division November 4, 1918. Because of exceedingly adverse weather conditions, Lieutenant Pendell disregarded the danger of fire from the ground and crossed the lines at 1,000 feet altitude. While thus flying he was wounded in the shoulder by an explosive bullet fired from the ground. Disregarding his wound, he came down to an altitude as low as 500 feet. After securing the desired information he wrote out his message with great effort and dropped it to the division. Home address, George C. Pendell, father, Caribou, Me.

First Lieut. John H. Lambert, pilot, Air Service, 91st Aero Squadron. For extraordinary heroism in action near Stenay, France, October 30, 1918. While on a photographic mission in the vicinity of Stenay, his work being seriously interfered with by the fire of a formation of enemy planes, Lieut. Lambert temporarily discontinued his mission, attacked the formation and dispersed it, destroying one plane and seriously damaging another. He then returned to his objective, completed his mission, and returned with information of great military value. Home address, Mrs. Joseph F. Kelley, 45 West Eleventh Street, New York, N. Y.

Capt. Everett R. Cook, pilot, Air Service, 91st Aero Squadron. For extraordinary heroism in action near Damvillers, France, September 26, 1918. While on a photographic mission in the vicinity of Damvillers, which necessitated a penetration of 20 kilometers within the enemy lines, Capt. Cook was attacked by seven enemy pursuit planes, and his plane was riddled with bullets. In spite of the attack he continued on his mission, turning only for our lines when his observer had secured photographs of great military value. In the combat one enemy aircraft was destroyed. Home address, Mrs. J. E. Cook, 232 Floyd Avenue, Toledo, Ohio.

First Lieut. John R. Cousins, Infantry, observer, 24th Aero Squadron. For extraordinary heroism in action near Conflans, France, November 2, 1918. In the course of a photographic mission of a particularly dangerous character, Lieut. Cousins and his pilot were attacked by a superior number of enemy pursuit planes. During the combat that ensued, with remarkable coolness and excellent shooting, he destroyed one of the attacking machines. Notwithstanding that the enemy aircraft continued to attack and harass them, Lieut. Cousins and pilot reached all their objectives and returned to our lines with photographs of great military importance. Home address, Mrs. J. A. Cousins, Whalley Avenue, Westville, Conn.

First Lieut. John H. Snyder, observer, Air Service, 1st Army. For extraordinary heroism in action September 12, 1918. While on a special mission to determine the probable enemy concentration in the back areas, Lieut. Snyder, with his pilot, in spite of almost impossible flying conditions, flew 60 kilometers over the enemy lines at a very low altitude. The unfavorable weather alone would have warranted them in turning back, but they continued on, regardless of very active and very accurate machine gun and antiaircraft fire. They returned to our lines when their mission was successfully completed. Home address, Mrs. William H. Noll, 319 North Sixth Street, Reading, Pa.

CIVILIAN FLYING OFFICIALLY SANCTIONED

THE Joint Army and Navy Board on Aeronautic Cognizance has issued the rules and regulations under which civilians may secure permission to fly. The application for such a license should be accompanied by the following information:

APPLICATION FOR LICENSE TO FLY CIVILIAN AIRCRAFT

License for flying civilian aircraft is desired under the following terms and conditions:

License to be issued to: ..... Address: .....
Owner: ..... Address: .....
To be operated by: ..... Address: .....
Date of first solo flight made by pilot.....
Date of designation as Reserve Military Aviator or Naval Aviator (and number) .....
Service in the U. S. Army or Navy.....
(An authenticated copy of a certificate or license as evidence of pilot's qualifications must be submitted.)
Passengers to be carried: .....
Description of aircraft: .....
Condition of planes: .....

THE JOINT ARMY & NAVY BOARD ON AERONAUTIC COGNIZANCE
Bldg. "D," 6th & B Sts., Washington, D. C.
L. G. Haugen, 1st Lieutenant, A. S. A.
Secretary.

INSTRUCTIONS TO LICENSEE

(1) All licensed aircraft shall display the license number in contrasting colors placed as follows:

Heavier-than-air craft: On the upper surface of each upper wing and the under surface of each lower wing.

Lighter-than-air craft: On the upper half and lower half, on opposite side from upper number.

All numbers will be five feet in height and nine inches in width of line, unless chord of wing is less than five feet, in which case height of numbers will equal wing chord, with above proportion of width of line.

(2) A monthly report is required from the holder of this License, giving the date, duration and number of flights made by the aircraft of this license number.

(3) This License is issued by the Board and accepted by the Licensee on condition that same may be revoked at any time the Board considers it necessary or desirable to do so.

(*Continued from page* 1068)

(6) From London to Brindisi, by way of Paris, Lyons, Marseilles, Turin, Florence, Rome.

(7) Across the Sahara Desert, from Algiers to Biskra, Ouargla, Bourassa, Timbuctoo, Koulikoro and Dakar.

I will now read an article on COMMERCIAL AVIATION IN THE LIGHT OF WAR EXPERIENCES, by Major-General Sir F. H. Sykes, K. C. B., C. M. G., Chief of the Air Staff (British), on Short Distance Passenger Services:

"I should like to say a few words on the prospects of individual passenger services between large centers separated only by a few hundred miles of distance. We have all been told in the papers how, before very long, business men and others will be telephoning to near-by aerodromes and ordering out their machines to convey them to Paris or Brussels or some other point. Well, there is morally no reason why this should not come about. It will interest you, I am sure, to hear what has been the experience of the Royal Air Force in this connection. Quite apart from the numbers of officers who have been transported to France in aeroplanes going out as reinforcements, we established in the summer of this year a small organization called the Communication Squadron. It was organized on comprehensive lines and consisted of two flights of D. H. 4s with Rolls Royce engines and a few other machines with a personnel of 61 officers and men. Between August and November there were made no fewer than 279 passenger cross-country flights such as to Paris, Nancy, Dunkirk, Manchester, York and Birmingham, and I am glad to say that there has not been a single case of a crash occurring to any machine with passengers on board. Many very distinguished people were transported, including several members of the British, French, American and Dominion Governments. One hundred and thirty-one visiting machines were also received and attended to. On one occasion two D. H. 4 machines were required to transport Mr. Paul Cravat and Mr. Crosby of the American Mission, and a record trip was made to Paris and back on the same day in four hours and twenty minutes. On another occasion a trip was made from Manchester, a distance of 170 miles, in an hour and twenty-five minutes, steering on a compass course above the clouds for a large portion of the distance. One of the pilots of this squadron, who is over 40 years old, has now flown across the Channel as pilot no less than 387 times, frequently in bad weather. Another organization which the Royal Air Force has found it necessary to maintain has been the single machine Channel Ferry from Lympne to Marquise, the establishment of which became necessary in order to rapidly return to England the large number of Ferry pilots who were engaged in taking out new machines to France. In this way it was possible to conduct the general dispatch of reinforcing machines to France with a smaller number of pilots. The results are of interest. During the four months of July, August, September and October of last year 227 trips were made, 8,085 miles were crossed, and 1,843 passengers transported. Of the 123 days in these four months, cross-channel flying was possible on 71 days, or approximately 60 per cent."

Are we going to stand inactive while other countries are going ahead aeronautically—and while one billion dollars' worth of aeroplanes, motors and equipment is deteriorating unused?

Aerial Transportation an Auxiliary to Water and Land Transportation

Aerial Transportation is here and is here to stay, as an auxiliary to land and water transportation. Aerial transportation bears the same relation to land and water transportation that the wireless bears to the regular mail and telegraph. It is unlimited by obstacles on land and water, curves are eliminated and there are no grades to climb after you reach your flying level.

When we enter the field of transportation of necessities and passengers, *speed* assumes exactly the relation which *cost* assumes when considering the transportation of coal on Ohio and Mississippi River barges, which are proverbial for snail-like progress as well as low cost.

Speed is a valuable factor in commerce as well as in war, and is desired by a large percentage of people in every walk of life, the means which have given greater speed in transportation and intercommunication have been well patronized.

Aerial transportation will be patronized because it affords greater speed. As an example one of the reasons passengers will travel by air in the near future is that it will be possible to leave New York in the morning and arrive in Chicago in the evening.

The great speed of the aeroplane makes it a valuable means of transportation, and many people will be glad to pay extra to have packages delivered in half the time required by other means of transportation.

It has been estimated that aerial express could be carried profitably at a charge of two dollars per pound for packages of a given size between New York and Chicago.

A twin-motored aeroplane can make the New York-Chicago trip in about seven hours, without stopping, carrying over one thousand pounds of express matter.

Such an aeroplane, made to order, will cost about $20,000. When built in large numbers they will cost probably only $10,000.

The life of the motors, if run throttled down, is about 500 hours of flying. The life of the plane is greater.

The Post Office has been operating an aerial mail line between New York and Washington daily since May 15, 1918, and has cut down the time for transit of mail between the two cities to two hours. Only small aeroplanes are used, which are more expensive to operate when figured on the ton per mile basis than large aeroplanes, yet the cost of operation, including all expenses, has been cut down to about forty cents per mile. It is cheaper than taxicab rates.

When large machines are employed and public aerodromes are in operation the cost of aerial transport may go down to less than one dollar per ton per mile.

British dirigible balloons, some of which are capable of carrying 60 tons of useful load, at a speed of over 60 miles an hour, may soon ply between Great Britain and the United States, carrying passengers, mail and express.

We Americans ought to be ashamed of our backwardness in this branch of aeronautics. The only dirigibles we have cannot carry a ton of useful load. They are small and slow, and we have only a few of them at that!

The field of lighter-than-air craft, German dirigibles of the

OFFICIAL STATUS OF AIR SERVICE FIELDS ANNOUNCED
In Operation January 20, 1919

Active Flying Fields — *Location*	*Commanding Officers*
Barron Field, Everman, Texas	Lt. Col. Thomas C. Turner.
Carlstrom Field, Arcadia, Florida	Major Horace M. Hickam.
Ellington Field, Houston, Texas	Lt. Col. Ira A. Rader.
Kelly Field, San Antonio, Texas	Colonel Henry C. Pratt.
Love Field, Dallas, Texas	Major Albert L. Sneed.
March Field, Riverside, California	Major John P. C. Bartholf.
Park Field, Millington, Tennessee	Major John W. Simmons, Jr.
Post Field, Ft. Sill, Oklahoma	Lt. Col. Richard B. Barnitz.
Rockwell Field, San Diego, California	Lt. Col. H. B. S. Burwell.
Inactive Fields	
Bolling Field, Anacostia, D. C.	Lt. Col. Ralph Hartz.
Brooks Field, San Antonio, Texas	Major John B. Brooks.
Call Field, Wichita Falls, Texas	Major James R. Alfonte.
Carruthers Field, Benbrook, Texas	Lt. Col. Jacob E. Fickel.
Chanute Field, Rantoul, Illinois	Lt. Col. Ira Longanecker.
Chapman Field, Miami, Florida	Major Jacob H. Rudolph.
Dorr Field, Arcadia, Florida	Major Horace M. Hickam.
Eberts Field, Lonoke, Arkansas	Lt. Col. Thomas Duncan.
Gerstner Field, Lake Charles, Louisiana	Lt. Col. William C. McChord.
Mather Field, Sacramento, California	Major Walter W. Wynne.
Payne Field, West Point, Mississippi	Major Ralph P. Cousins.
Rich Field, Waco, Texas	Major John G. Whitesides.
Selfridge Field, Mt. Clemens, Michigan	Major Frank D. Lackland.
Scott Field, Belleville, Illinois	Major Henry Abbey.
Souther Field, Americus, Georgia	Lt. Col. Frederick T. Dickman.
Taliaferro Field, Hicks, Texas	Major Theodore C. McCauley.
Taylor Field, Montgomery, Alabama	Lt. Col. Seth W. Cook.
Camp Dick, (Cadet Gunnery Camp), Dallas, Texas	1st Lt. Ormsby McCammon, Acting
Langley Field, Hampton, Virginia	Major Clinton W. Howard.
Wilbur Wright Field, (Armorers School), Fairfield, Ohio	Lt. Col. Henry C. K. Muhlenberg.
Provisional Wings	
1st Provisional Wing, (Active), Hazelhurst, Long Island	Lt. Col. Millard F. Harmon, Jr.
Brindley Field, (Active), Commack, Long Island	Major H. H. C. Richards.
Henry J. Damm Field, (Active), Babylon, Long Island	Major E. Lyons.
Hazelhurst Field, (Active), Mineola, Long Island	Lt. Col. Millard F. Harmon, Jr.
Lufbery Field, (Active), Wantaugh, Long Island	1st Lt. W. B. Maurice.
Mitchell Field, (Active), Mineola, Long Island	Major H. M. Clark.
Roosevelt Field, (Active), Mineola, Long Island	Major Richard D. Gile.
2nd Provisional Wing, (Inactive) Park Place, Texas	Major Roy S. Brown.
Ground Schools	
Schools of Military Aeronautics:	
University of California, Berkeley, California	Major Chas. B. Crane.
*Cornell University, Ithaca, New York	Major Harral Mulliken.
*University of Illinois, Urbana, Illinois	Capt. Frank C. Hendry.
University of Texas, Austin, Texas	Capt. Herbert G. Knight.

*Discontinued training preparatory to being closed.

A Curtiss Flying Boat, of the type that bids well to become extraordinarily popular with sportsmen this year, making an excellent landing

FOREIGN NEWS

General Pershing Authorized to Grant Promotions to Officers

General Pershing has been authorized by the Secretary of War to grant promotions to officers up to and including the rank of Colonel. These promotions shall not be made merely as a reward for past service, but the effect of the order will be to permit many promotions which were unjustly excluded by the order issued immediately after the signing of the armistice.

Lieut. Nungesser to Accompany Fonck to U. S.

Paris, Feb. 2.—Sub-Lieutenant Nungesser, who gained more than forty-four aerial victories over the Germans, will accompany Rene Fonck, the leading French ace, when Fonck comes to the United States in a few days to attend the annual dinner of the Aero Club of America. The aviators will be accompanied by Robert Esnaul Pelterie, president of the Aeronautic Industries Association of France.

Ipswich to India Flight Held Up

The Handley Page aeroplane in which General MacEwen started from Ipswich to fly to India, and which was detained by bad weather at Mersa and Matruh, arrived at Heliopolis on January 3. It resumed its journey on the morning of January 12. No further report has been received regarding the progress of the flight.

British Government Refuses Air Route License

The British Government has declined to register a company formed to promote air services between London and Sydney, says the *Times* correspondent at Sydney. He adds that a statement has been issued implying that Mr. Hughes has arranged for a Government monopoly for this air route.

French Air Minister Resigns

Paris.—It was announced on January 9 that M. Dumesnil, Under-Secretary of State for Aviation, has resigned, primarily because of the decision of the Government to bring naval and military aeronautics under the Ministry of War. M. Clemenceau has expressed his regret that, owing to the reorganization of the War Ministry, it has become necessary for M. Dumesnil to relinquish his duties, and says that M. Dumesnil had succeeded in equipping France with an aviation service worthy of her Army.

Transatlantic Flight Soon, Says General Brancker

London, Feb. 2.—The Atlantic ocean certainly will be crossed by an aircraft this spring, probably by an American aeroplane, Gen. Sir William Brancker declared to the correspondent of *The Sun*.

The Aircraft Manufacturing Company, with which Gen. Brancker is actively connected, already is planning a transatlantic flight, using either a D. H. 10, one of the famous war bombing planes fitted with two 345 horse-power Rolls-Royce engines, giving a speed of 120 miles an hour and a duration of flight of 2,000 miles, or a new machine not yet completed fitted with one 600 horse-power engine with a speed of 125 miles an hour and a duration of 2,500 miles.

The flight will be made from east to west, the machine carrying two men, a navigator who will have charge of the flight and a pilot.

"The machine which has been selected by the Air Ministry for the attempt is a flying boat, similar in every way to those which did such valuable work as coastal patrols during the war. It is known as the Felixstowe, in commemoration of the station where it was built on the designs of Lieut. John Cyril Porte, the famous British airman who waited all the summer of 1914 on the American coast in the hope of being able to make the flight.

The machine is a triplane, with five engines of 375 horse-power, driving two tractor and three pusher airscrews. The extreme length of the wings is 123 feet, of the hull from nose to tail 60 feet. When the machine has completed its trials it will be dismantled and sent to America, where it will be reassembled for the flight."

Commercial Aeronautic Possibilities in South Africa

A London aeronautic publication has discussed the future of commercial aeronautics in South Africa in a recent issue which indicates the progressive attitude of the British industry.

Realizing that for the present the most important function that aeronautic transport can accomplish is the delivery of mails and passengers, in this respect, conditions in South Africa are especially conducive to aerial commerce. The population is small, but wealthy and active. Distance between cities is large and railroad communication poor. The railways follow the contour of the hills, having been built at so much per mile. The contractors therefore avoided bridges, tunnels, and embankments. Grades of one in forty are numerous. The windings and contortions of the snake-like tracks make it seem quite possible in many places to shake hands with the engineer in the rear car. The ever-present sand and dust are especially disagreeable. These conditions, as compared with cool and speedy transportation by aeroplane, would make it difficult for railroads to compete with well-organized aerial passenger lines.

The stable weather conditions, absence of hurricanes, and high winds, extreme clearness of the atmosphere, the definite rainy season on only one short fixed period of the year make conditions excellent for reliable air travel.

The natural wealth of the Union, not only in precious metals and minerals, but in the whole range of natural resources, as well as its ability to supply many of the necessary materials for the maintenance of commercial aircraft, makes the prospects of an enterprising aircraft organization most excellent. Alcohol suitable for fuel is produced in considerable quantities and the climate in some parts is suitable for spruce growing. Land is available for aerodromes at low rates.

The details of various routes are outlined in the article. The first route is suggested from Cape Town to Kimberly, 525 miles air line. The train service between these important points consists of two trains each way daily, with a running time of thirty hours. The estimated time by air, allowing for stops, is eight hours.

A route from Kimberly to Johannesburg requiring 45 hours by rail, could be covered by aeroplane in twelve hours. From Kimberly to Durban a saving of thirty-six hours could be made, the time by rail being forty-one hours and by plane five and a half hours.

The ultimate expansion of an aerial transport system would result in a route from Cape Town to Cairo.

Build Super-Airships

London, Jan. 13.—The *Evening News* announced today that the admiralty is building "super-airships" with a cruising radius of 8,000 miles. They would carry a crew of twenty-five persons and have a speed of seventy to eighty miles an hour.

Caproni Biplane Carries Ten Passengers Three Hundred Miles

Rome.—A Caproni Biplane carrying ten passengers flew from Milan to Rome in four hours carrying ten passengers. The distance is 300 miles.

British Planes To Take Food To Belgium Daily

London, Jan. 31.—The Government has allotted a squadron of military aeroplanes to convey foodstuffs to Belgium for the relief of the population. The service, which is to be daily, will begin immediately between Folkestone and Ghent.

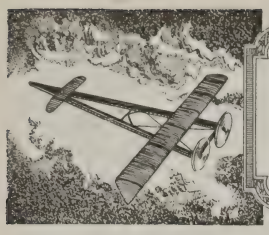
Keep British Air Force Young Men's Service

London, January 28 (Via. Montreal).—Regulations just issued show that the authorities here are determined to maintain the air force as a young man's service. No colonel over forty-eight will be allowed to remain in the force unless he has had three years' service in war.

A special board has been appointed to investigate all candidates for permanent commissions. Future pay allowances will not necessarily be as good as those now in force.

Japan Establishing Additional Military Aeronautic Schools

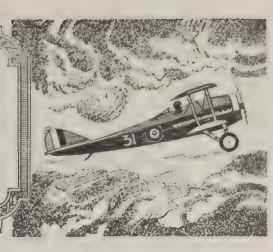
Tokio, Japan.—The budget presented by the Japanese War Depart- inaugurating new undertakings. Two million of this is desired for ment for the coming fiscal year includes ten million dollars for the establishment of a military aviation school near Tokio and three million dollars for the expansion of the Japanese Air Service. Japan has already established a powerful air service and is profiting from allied experience in the war.



Triple-motored 1916 Caproni Biplane with rotary motors

Aeroplanes Added to Equipment of Northwest Mounted Police

Ottawa, Jan. 28.—The government announced that aeroplanes would be added to the equipment of the Northwest Mounted Police for their work in the frozen north.



Air Conference to Have 25 Delegates

Paris.—As announced in previous issues, a conference will be held in the early part of February for framing international air laws. It has been announced that there will be five delegates each from France, Great Britain, Belgium, Italy, and the United States. The conclusion of this committee will be presented in the peace conference for discussion and adoption.

ELEMENTARY AERONAUTICS *and* MODEL NOTES

By John F. McMahon

Model Aeroplane Building as a Step to Aeronautical Engineering

A FEW fittings are shown in the accompanying cut as well as a photo of the installation of a Ford motor in an aeroplane.

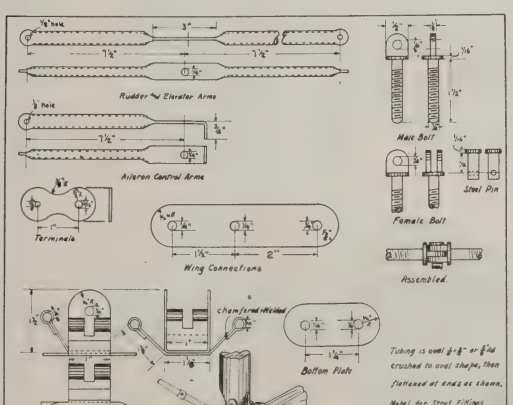
This photograph is of the mounting of the motor in Mr. E. H. Holterman's machine and the reader can get a very good idea of the general arrangements. Note that the engine is turned just the reverse to what it would be in an automobile; in order words, the crank handle end is in the rear now facing the pilot, while the fly wheel end is in front to which is bolted a special propeller hub that extends outward through a hole in the radiator. The reader can see the carburetor and magneto mounting as well as the specially made oil pan. This pan was made of sheet aluminum.

There are no exhaust pipes in place in the photograph, but they are attached by special clamps to the engine bolts.

Detail drawings of the Ford changes will be given on this page as soon as we get sufficient space for them.

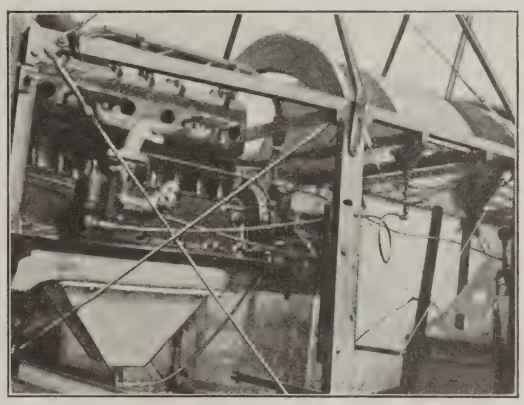
The fittings shown below are the elevator and rudder arms and also the aileron arm. These are made of good strong 1/32" wall steel tubing and of oval shape. It is not always possible to purchase oval tubing ¾ x ½" so you can get ⅝" round and crush it to the desired shape. The long ones are needed, two for the elevator flaps and one for the rudder. Four short ones for the ailerons are needed. One for each aileron. The reader will note that the arms are fastened on top, to the top ailerons, and to the bottom of the lower ailerons.

The terminal plate shown is for use where all wires are to be fastened and where no other plate has been provided. For instance, the brace wires to the Fin, brace wires to the tail spars, where the control wires attach to the end, of ailerons, rudder, and flaps, etc.



The plate is made from .050" cold rolled steel.

The wing connection plates are made of 1/10" or .090 cold rolled. Either thickness will do as the variation is not much and the builder can use the size which he can purchase the easiest.



These plates are fastened to the wing spars, two being used on each spar and fastened with two bolts, two are also fastened to each end of the center section spar, a ¼" pin holding them together. 24 of these are needed.

The aileron, tail flap, and rudder hinges are shown at the upper right hand corner.

This is simply made of two ¼" special bolts, one having a forked end, the other having but one tongue which fits between the forked ends of the other and is held by a ¼" pin which is in turn held from falling out of place by a cotter pin. It is necessary to make 14 of these hinges. Two to each aileron, rudder, and elevator flap.

Details of fittings for the Ford motored aeroplane

Ford motor installed in an aeroplane

When setting these in place it would be advisable to cut a recess or drill a sort of a well out of the spar to allow the fitting to sink in a little deeper, to diminish the space between the main or stationary, and moving parts.

It might be a good time to tell the reader that all surplus ends on bolts and fittings should be cut off, as they should be no longer than is necessary because they only add a lot of weight without increasing the strength.

The lower fitting is the interplane strut fitting and is for attaching the struts and fastening the bracing wires too. This fitting is very simple and its strength is many times greater than is necessary.

Twenty of these fittings are needed. If you are not familiar with welding of metals I would advise that you have this work done by experts as the strength of this fitting depends on the strength of the jointed part.

The sketch shows clearly how the fitting is used, especially the setting of the bottom plate under the spar.

On the eight outside fittings one of the terminals can be cut off to save weight as only two, a side and rear connection, are needed.

(To be continued)

Model Aeroplane Contests

THE proposed model aeroplane contests which was announced to begin in the Spring seem to have met with considerable interest as the Model Department has been fairly swamped with letters and post cards asking for permission to enter one or more of the contests.

Some readers seem to think that they are late and cannot enter, which is a wrong impression as nothing has been decided on as yet.

There is plenty of time for every model reader or flyer in the United States and Canada to get in line. The style or order of events will be announced later.

A prominent member of the Aero Club of America has promised to offer a valuable prize for one of these contests and I am sure a few more well-known aeronautical men will follow up this kind offer.

The contests will not be for model flying alone, but for best design, construction, etc.

The readers who have not as yet sent in their names should do so at once, to enable us to estimate approximately the number of contestants, as the value of the prizes will no doubt be in proportion to the entry list.

We want the entry list to be big, and it would be well for those who are interested in this page to get your friends in line, as the benefits derived from model flying are many, and although a beginner may not win a prize this time, he will be a veteran when the next contests come around.

Send postal or letters to the Model Editor!

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Prohibition as a Boon to Aeronautics

Charles Walsh, proprietor of a large hotel in Connecticut well known to yachtsmen, motorists and aeronauts, is going to incorporate a company to build dirigible saloons. The possibilities of aeronautics loom larger and larger each day, as we realize that thousands of new aeronautic enthusiasts will swell our ranks in order to visit Charlie's gin mills.

We asked Charlie how we would land on his aerial oasis as we fly by in our 1920 Aerial Bullet.

"That will have to be worked out," he admitted, "but it could be arranged to hook patrons aboard from passing planes by some such device as that which hooks mail sacks off a passing train at rural stations. Or maybe the planes can be throttled down so visitors can step off. That is a minor detail. A thirsty man will dive off, if necessary."

Here we interposed and pointed to the recent feat of one of our military aviators in dropping from one plane in flight to another a few feet below. This had doubtless been done in anticipation of the establishment of the Walsh chain of Aerial Saloons.

Charlie's vision filled our hearts with hope and for the first time since Prohibition had been ratified did we feel like breathing freely. We could visualize ourselves imbibing stimulating spirits and laughing at the impotent constitution whose all embracing arm could not reach the heavens above.

"The sale of liquor may be legal in the air, but how can you get the stuff when it can't be manufactured on land?" asked one of our number.

Fortunately Charlie's answer was prompt, which saved me from heart-failure.

"Dirigible breweries and distilleries," he declared with a wave of the hand. "I have it on the authority of a chemist that at 3,500 feet the atmosphere is ideal for rapid distillation. But you must understand that there will be great quantities of liquors on hand long after the bone dry law goes into effect. The problem will be to sell them, and the dirigible will solve it."

"But the danger of men getting under the influence of drink and becoming careless to the point where they may topple off the air cafe," suggested one of our number.

"A man can stand much more drink in the higher altitude than on the ground," explained Mr. Walsh. "It is possible a drinker may consume incessantly at certain heights and never feel a flicker. You never heard of drunkenness on top of the Himalaya Mountains, did you?"

"No, but——"

Just then Big Ben woke me up to another day's work in this dry, dry world.

Found in a Bachelor's Room

A bird—a bottle,
An open-work stocking.
Some might think this awfully shocking, alas;
The bottle was empty
The bird a stuffed one
The open-work stocking
Needed mending some.

Twentieth Century Lament

Little Jack Horner, sat in a corner,
Eating some kind of a pie.
He stuck in his thumb
And looked awful glum
Then said, "Why in h—— can't I fly?"

Welcome Home, Airmen

Suggested menus for home-coming celebrations by AERIAL AGE's Culinary Editors:

Soups

Cream of Stall — Puree a la Side Slip

Relishes

Sliced Reversements
Combination Landing Salad
Falling Leaf With Zeroline Dressing
Fish
Fried Fillet of Loops

Entrees

Fried Wing Overs — Zoom Cutlets
Roast a la Bumble Bee

Desserts

Nose Dive Special — Whipp Stalls

Drinks

Dropinbay Highball — Highfog Flip
Tail Spin Rickey

SALADS

Tail Spin Fruit
Celery Hearts (broken)
Footballs La Petit

ENTREES

Baked Ornithopter, Immelman Sauce
Dressing (Oyster A. W. O. L.)
Giblet Gravy (Camouflaged)
Baked Chassis
Smashed Spads — Candied Fuselage
French Ballbearings
Cream Flowers

DESSERTS

Sideslip — Blighty Pudding
Phosfer Bronze Sauce
Exhaust — Intake
Wing Dope
Kentucy Julip Greens

METROPOLITAN MOVIES.

"Gee whiz, Jimmy! I'll betcha them's aojers in that there flyin' machine."
"Aw, g'wan! Soldiers nothin'! Them's the bugs what kses the prices of milk."

Safety First in Aeronautics

If you fly straight,
There is no need to worry;
If you fly improperly,
Of two things one is certain—
Either you spin or you don't.
If you don't spin,
There is no need to worry;
If you do spin,
Of two things one is certain—
Either you crash or you don't.
If you do not crash,
There is no need to worry;
If you do crash,
Of two things one is certain—
Either you are hurt slightly or seriously.
If you are hurt slightly,
There is no need to worry;
If you are hurt seriously,
Of two things one is certain—
Either you recover or you die.
If you recover,
There is no need to worry;
If you die, you cannot worry.

Zeppelin type have many long and sustained flights. One well authenticated report states that a dirigible flew from Jamboli in Bulgaria, carrying twenty-two men, 28 tons of medicines and supplies to one of the German Generals, Lettow-Vorbeck, in German East Africa. When the airship arrived over Khartoum it received a wireless message that the General had surrendered. It then returned without landing, having covered nearly four thousand miles, and remained in the air 96 hours.

England has built rigid dirigibles up to 70 tons capacity, with a speed of 78 miles per hour, and has projected still larger ones of 200 tons, 1,000 feet in length, 154 feet in diameter, to contain 10,000,000 cubic feet of gas, with a speed of 85 miles per hour, and have a cruising radius that would take them around the world. Inflated with non-inflammable gas such great airships, flocks of swift, small aeroplanes, giant cargo machines and flying boats, will soon solve our problems of rapid transportation and intercommunication over land and sea, ice and snow, mountains, plains, rivers, lakes, forests, swamps and deserts and make every city in the land a port on the great ocean of Atmosphere.

Aeroplanes capable of lifting from fifteen to twenty tons are already in operation. The Curtiss Naval seaplane "NC1" equipped with three Liberty motors, recently carried fifty-one passengers in one flight. The large Handley-Page biplane, equipped with four Rolls-Royce motors, recently carried 40 passengers on a flight and then flew from London to Africa with twelve passengers. A Rolls-Royce motor ran for seven days without stopping on a block test, at 2,000 r.p.m.

Recommendations for the Solution of National Aeronautic Problems

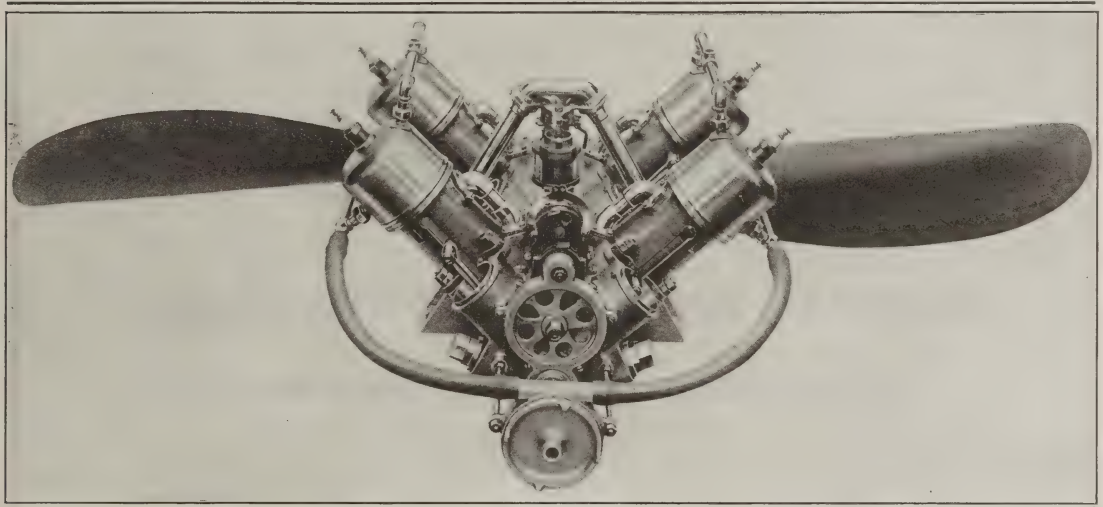
As the subject is new and confusing to most people, and the national aeronautic problems are very serious and pressing, we have, to facilitate matters, outlined a few recommendations for actions which should be taken in the near future.

We recommend (1) The organization of a Government organization similar to the Grain Corporation, to be known as the Aerial Transportation Corporation, or a similar name, capitalized at $50,000,000, which shall take over the $800,000,000 worth of aeroplanes, motors, and aeronautic equipment which the Army and Navy cannot use and are trying to dispose of. This corporation shall devise ways and means for salvaging this equipment, utilizing whatever can be used to establish aerial transportation lines in the United States and supplying the South and Central American countries which are anxious to have aerial transportation lines.

(2) Let this Government owned Aerial Transport Company take over the twenty or so Army aviation stations and aviation depots which the Army has abandoned or is abandoning and operate them as public aerodromes where the Post Office as well as civilian aviators can use the hangars and facilities by paying rent.

(3) Let this corporation establish and operate aerial transport lines between industrial centers. Some of these lines can run from New York to San Francisco, from Washington to Chicago, from Minneapolis to New Orleans, from New Orleans to New York, from Seattle and Portland, Oregon, to San Francisco, Los Angeles and San Diego, from Detroit to St. Paul, from Key West to Havana, from Portland, Maine, to Boston and New York. Scores of such aerial transportation lines could be established and operated immediately, employing some of the thousands of idle Army and Navy aviators and mechanics, and they would solve the difficult national problems of transportation, solving the problem of utilizing the idle equipment and employing the idle aviators.

(4) All air traffic should be classed with interstate and international traffic and the interstate traffic regulations should be extended to include air traffic.



(5) The Department of Commerce should be given charge of the registration and inspection of aircraft, creating in the Department of Commerce an Aircraft Inspection service similar to the present Steamboat Inspection Service.

The subject is most extensive and the time available is limited. I will not, therefore, discuss in detail the regulations that have been proposed by the British Aerial Transport Committee, a copy of which I have with me and will be glad to show to any person who is interested in the subject. I also have a number of copies of *Flying*, the leading aeronautic magazine, which contains an article on serial regulations by Mr. Henry Woodhouse, who is considered the best posted man in aeronautics in America. He has made a close study of the aerial regulations of different countries in the past ten years and his article shows by actual illustrations how some of the most difficult problems of enforcing the aerial regulations can be solved by using the wireless telephones developed by Colonel C. C. Culver, and in other ways. I will be glad to give copies of *Flying*, containing Mr. Woodhouse's able article, to any person who wishes a copy.

large extent the entrance of interfering noises. These earpieces are mounted in the helmet and consist of pneumatic cushions or rings which surround the ear and maintain an airtight contact with the head with but small pressure. They are very efficient as well as comfortable.

Three headpiece designs consist in:

2. The use of a soft helmet.

1. The use of a hard helmet.

3. The use of any helmet, the earpieces being attached to an elastic head band and worn underneath any helmet.

The second governing condition relating to the design of the voice duct and requiring the maximum intensity ratio of voice sound to aeroplane noises is a matter which demands the closest attention in securing the best results.

Tube length—Except for very short tube length, there is a definite length which will give best results for a given aeroplane. In as much as the motor exhaust noises are the most powerful that have to be contended with and as they are periodic with a fairly uniform frequency they can be reckoned with on this basis: tube lengths equal to ¼, ¾, 5/4, etc., of the wave length of these motor exhaust sounds must be avoided in order to prevent amplification of those sounds by resonance.

Tube Diameter—A consideration of the limiting values indicates that an optimum tube diameter.

An infinitely small tube, it is evident, could offer an infinitely high resistance to the propogation of the voice vibration. On the other hand, an infinitely large tube would duplicate the conditions applying in talking directly through the open air, which, as has previously been pointed out, is impossible. In general, that tube length is to be preferred which will transmit the aeroplane noises with no greater intensity than those reaching the ears around the ear caps.

Tube Walls—The material comprising the walls of the tube, aside from the requirements as to flexibility, light weight, durability, etc., must prevent both the escape of voice sounds and the entrance of aeroplane noises and in addition the inside surface should be such as to break up any tendancy of the enclosed air columns to oscillate freely.

This is desirable firstly so that the air column is in a periodic vibrating body, which is necessary in order to prevent distortion, and secondly, so that it will form a very poor resonator to any periodic aeroplane noises which otherwise might be amplified by resonance.

All of these more important factors as well as others of a purely practical nature have determined the designs of the aeroplane and the highly satisfactory results obtained wherever it has been used testify eloquently to the wisdom of this course as distinguished from a design based only upon cut-and-try guesswork. As distinguished in the telephone method of communication the speaking tube has the additional great inherent advantage of requiring no vibratory diaphragms in the sound passage from the speaker to the listener. These are of course a necessary evil in the electrical transmission of speech for they not only distort many of the transmitted speech sounds out of all true similarities actuating vibrations, but they also hinder or prevent entirely the transmission of many of the complex vibrations comprising articulate speech. The result is, that only the nearest skeleton of a spoken word is trasnmitted and this explains the fact that, when unassisted by the context of telephone speech, such a very low percentage of words can be understood even with the best telephone equipment and without noise interference.

For such aircraft as are equipped with radio reception apparatus, a combination radio and airfone helmet has been desounds, as well as the radio signals or speech reach the ears through a common or combined earpiece so that these communications may be received separately or simultaneously, as desired by the radio operator.

The Airfone has indeed proven an admirable solution of this heretofore perplexing problem of pilot-observer communication—and it fills a strongly felt need in this whole field of aviation.

(*Continued from page* 1082)

trol cables run to their trailing edges, and a compensating cable runs through the fin from the leading edge of one rudder to the leading edge of the other.

Landing Gear

The landing gear comprises four 2'-11-7/16" diameter wheels with tires 7⅞" wide. Wheels arranged in two pairs, each pair having a 4'-6" tread, and inner wheels spaced 5'-8⅛" from center to center.

Axles are hinged at center. Vertical shock absorber mechanism enclosed in an aluminum casing.

Tail skid is the usual swivelled pylon-mounted ash skid, shod with a sheet steel plate.

Engines

The Liberty engines are entirely enclosed in streamlined sheet aluminum nacelles between the planes. Propeller axes 10'-11-1/16" above ground when machine is in flying position.

Propellers 10'-6" diameter, both revolving in the same direction.

Radiator faces have adjustable shutters to regulate the air admittance. Water capacity of radiators, 300 lbs.

Each of the two Liberty "12" engines gives 400 h.p. at 1.625 r.p.m. Bore and stroke 5 x 7 inches. Fuel consumption, .55 lbs. per h.p. hour; oil, .03 lbs. per h.p. hour. Engine weight, 3,044 lbs. with propeller.

Tanks located above bomb compartment. Fuel capacity, 280 gallons; oil, 15.3 gallons.

U. S. NAVAL AVIATORS PLAN TRANS-ATLANTIC FLIGHT

THE announcement that the Navy Department has ordered Commander John H. Towers to take charge of "the development of plans and assembly of material and personnel for the proposed transatlantic flight" is very gratifying.

The matter of transatlantic flight has been a source of some anxiety to progressive Americans who rightly feel that the country of the Wrights, and Curtiss and other pioneers should be first in achieving this epoch making flight especially as America, through the progressive efforts of Mr. Rodman Wanamaker in 1914, was first to take up the subject seriously.

The announcement of the Navy Department came in an order from Secretary Daniels detailing Commander John H. Towers, who has been attached to the office of naval operations, to take charge of the development of plans and the assembly of material for the proposed trip. He will map out the route to be followed, make the arrangements for the momentous journey and probably recommend to the Secretary the men who will make up the crew of the airship in which it is to be made.

The fact that the navy was making ready for this enterprise and that Commander Tower had been ordered to take charge of the work was disclosed inadvertently. Nothing was to have been said until it was well under way. It is evidently the purpose of the Navy Department to win the distinction of being the first to make a successful flight across the ocean.

It is fitting that Commander Towers should have been selected to organize this flight. He was one of the two first naval officers in the world to take up aeronautics, the other being Lieut. Commander Theodore G. Ellison. Subsequently he was the representative of the Navy in co-operating with Mr. Rodman Wanamaker in the organization of the transatlantic flight in 1914, which was prevented by the advent of the war.

There are a number of other transatlantic projects under way, therefore America stands a good chance of being first to achieve this flight, which is to be an historic event in the annals of aeronautic history.

APPROPRIATION FOR LARGE DIRIGIBLES SHOULD BE GRANTED

THE appropriation requested by the Navy Department for large dirigibles should be granted.

America has been retrogressive in this branch of aeronautics, as it has been in all other branches, and has paid dearly for her retrogressiveness.

Had we had six large dirigibles, the patrolling of the Atlantic to protect shipping from U-boats would have been easy, and patrolling our coasts would have been easier still.

The loss to America, due to the number of American ships sunk in American waters was greater than it would have cost to build a fleet of fifty large dirigibles.

Dirigibles can be built of enormous size. The following quoted from Mr. Alan R. Hawley's address to the convention of the Rivers and Harbors Congress gives a good idea of what can be done in this branch of aeronautics.

"We Americans ought to be ashamed of our backwardness in this branch of aeronautics. The only dirigibles we have cannot carry a ton of useful load. They are small and slow, and we have only a few of them at that!

The field of lighter-than-air craft, German dirigibles of the Zeppelin type have many long and sustained flights. One well authenticated report states that a dirigible flew from Jamboli in Bulgaria, carrying twenty-two men, 28 tons of medicines and supplies to one of the German Generals, Lettow-Vorbeck, in German East Africa. When the airship arrived over Khartoum it received a wireless message that the General had surrendered. It then returned without landing, having covered nearly four thousand miles, and remained in the air 96 hours.

"England has built rigid dirigibles up to 70 tons capacity, with a speed of 78 miles per hour, and has projected still larger ones of 200 tons, 1,000 feet in length, 154 feet in diameter, to contain 10,000,000 cubic feet of gas, with a speed of 85 miles per hour, and have a cruising radius that would take them around the world. Inflated with non-inflammable gas such great airships, flocks of swift, small aeroplanes, giant cargo machines and flying boats, will soon solve our problems of rapid transportation and intercommunication over land and sea, ice and snow, mountains, plains, rivers, lakes, forests, swamps and deserts and make every city in the land a port on the great ocean of Atmosphere."

If we are to maintain our position in the aeronautic world of to-day, it is most important that the appropriation for the large dirigibles be granted.

PLANS COMPLETE FOR AERO CLUB BANQUET

PLANS have now been completed for the 13th Annual Banquet of the Aero Club of America to be held at the Waldorf-Astoria on February 19th.

Lieut. Rene Fonck, ace of all aces, who has an official record of 75 German machines to his credit, and an unofficial record of 125 machines, and who on two occasions has brought down six machines in one day, has been granted permission by the French Government to attend the 13th Annual Banquet of the Aero Club of America, and will be the guest of honor.

Lieut. Charles Nungesser, second in the list of French aces, and Robert Esnault Pelterie, president of the Aeronautic industries association of France, are accompanying Lieut. Fonck and will be present at the banquet.

Among the other aces expected to be present are, Colonel William A. Bishop, V.C., D.S.O., M.C., D.F.C.; Lieut. Colonel William Thaw, Captain Edward V. Rickenbacker, Major James A. Meissner, Captain Arthur J. Coyle, in command of the 1st Aero Squadron and one of the 300 aviators trained by the Aero Club of America in 1915-16, and as many of the American Aviation Officers from the front as are free to attend on that evening.

Rear Admiral Robert E. Peary has accepted an invitation to speak upon "Exploration by Aeroplane" and the opportunity for great aerial transportation systems to be extended all over the United States.

Major General Charles T. Menoher, Director of the Air Service, will speak on Military Aeronautics, and Rear Admiral Bradley A. Fiske, U. S. N., retired, will speak upon recent developments in maritime Aeronautics.

Mr. John Hays Hammond will speak on the subject of "Polar Aero Radio Survey."

The Honorable Fiorello H. La Guardia, Major in the Air Service and Member of Congress, will speak upon the wonderful developments in aviation in Italy, and an invitation has been extended to Signor Gianni Caproni, who is expected to arrive in this country.

Mr. Alan R. Hawley will preside and Mr. Henry A. Wise Wood will be toastmaster.

Arrangements have been made for ladies to hear the speeches from the boxes, to which they will be admitted any time after eight o'clock. Cards of admission may be obtained by subscribers to the banquet.

IDLE WINGS

WE printed last week the able address delivered by Mr. Alan R. Hawley, president of the Aero Club of America to the convention of the Rivers and Harbors Congress, in which he proposed a practical solution to the national aeronautic problems including the problem of utilizing idle army and navy aircraft, motors and aeronautic equipment and the employing of thousands of the army and navy aviators. The *N. Y. Tribune* gives a leading editorial to the subject endorsing Mr. Hawley's recommendations as follows:

Considered as a matter of dollars and cents:

The United States has trained 30,000 army and navy pilots, at an average cost of $10,000 each, a total of $300,000,000.

The United States has on hand aeronautic equipment valued at $800,000,000.

Dismissing as a closed incident the fact that our lack of aerial preparedness resulted in comparatively few of these trained pilots getting into the fighting and in only 102 American aeroplanes reaching the front, can we, rich as we are, afford to let $1,100,000,000 expended for training and material go to waste? That sum is only a small part of the amount dispensed. Those 30,000 men, for instance, were only the expert pilots. According to Secretary Baker, the day of the armistice saw 18,688 officers and 137,760 enlisted men in the air service.

But those 30,000 expert pilots and that $800,000,000 worth of material represent the assets of a concern that has gone out of business. What shall be done with these assets? Shall these young men who have qualified for the conquest of the air go back to the counter, the office and the shop? Shall this vast amount of material, the finest of motors, the pick of the spruce forests, the best product of the linen looms, decay in government warehouses while the United States, after giving the world the first practical aeroplane, relapses to the last place in aeronautics, which it held at the outbreak of the war?

The questions will have to be answered one way or the other very soon. Our aviators, discharged from the service, are asking what is in store for them. Captain Eddie Rickenbacker, the American ace of aces, talking of his plans for the future, said he could not imagine himself returning to his old profession of motor racing. He has definitely cut the bonds that bind him to the earth and expects the air to be his realm in the future. In the case of Captain Rickenbacker there will be no lack of opportunity to follow this chosen course, but what of the thousands of other young men just as eager for the new life, who, not having won the renown which attaches to an ace of aces, will not find so many opportunities open to them?

One answer is that proposed by Alan R. Hawley, president of the Aero Club of America, in an address at the convention of the Rivers and Harbors Congress in Washington. Captain Hawley proposed that the energy engendered by war be not permitted to die, but be turned while it is still under full momentum into the channels of commerce. The pith of the plan is in this paragraph:

"The organization of a government body similar to the grain corporation, to be known as the Aerial Transport Corporation or by a similar name, capitalized at $50,000,000, which shall take over the $800,000,000 worth of aeroplanes, motors and aeronautic equipment which the army and navy cannot use and are trying to dispose of. The corporation shall devise ways and means for salvaging this equipment, utilizing whatever can be used to establish aerial transportation lines in the United States and supplying the South and Central American countries, which are anxious to have aerial transportation lines."

Definite suggestions are put forth for the establishment of aerial transport lines connecting industrial centres, such as New York and San Francisco, Washington and Chicago, Minneapolis and New Orleans, Key West and Havana, and the like. The corporation would take over all the material the government has on hand and would give employment to such of the government-trained aviators as wish to continue the career in the air opened to them through their training for war.

There are twenty or more army aviation stations and aviation depots which this aerial transport corporation would take over and operate as public airdromes which could be used, by the payment of a fee, by private as well as government aviators, the latter being employed in such tasks as carrying mail. Such airdromes, by the way, are springing up in all parts of England, aerial transport is being established on a large scale, and a type of low-priced machine is being turned out for civilian fliers and is finding a large sale.

Bills now before Congress call for a peace program for the army which will make use of less than 2,500 pilots, and that of the navy calls for the retention of only 350 aviators of the present 10,000 flying men in that service. If the army and navy are to be reduced to such a footing it seems to be the part of wisdom for the government to provide some such possible auxiliary as would be afforded by the Aerial Transport Corporation.

THE HOMING AIRMEN

The flags halfstaff for Roosevelt fly
As back our airmen come,
The greetings not the bugle call
Our thrilling roll of drum.
We greet them with a half choked voice
And beating of the heart,
At thought of what these boys have faced,
And how they did their part.
We read within their dauntless eyes
The deeds that they have done,
Those eyes that once flashed forth the flame
That hurled to earth the Hun.

Some flushed by victory and fame
Like homing eagles soar,
Some torn by fury of the fight
Shall fly the skies no more.
But in our hearts fond memory keeps
A votive flame aglow,
For all who answered freedom's call
And headed for the foe.
And darting through despair's black cloud
Like fierce beams of the sun,
For our battalions blazed the way
Till abject quailed the Hun.

J. E. KELLY

THE NEWS OF THE WEEK

Aeronautic Exposition Plans Developing

Official Government exhibits for the aeronautical exposition of the Manufacturers Aircraft Association are being shipped to naval depots and army flying fields near New York City. At these places the planes and motors will be prepared for truck transportation to Madison Square Garden and the Sixty-ninth Regiment Armory, where, March 1 to 15, the exposition will be held.

It is now definitely known that the greatest types of aircraft from the United States, Great Britain and Italy will be on display, the Navy NC-1 and an all-American bomber being placed in the Garden and a Handley-Page and an Italian Government Caproni in the Sixty-ninth Regiment Armory. In the Garden, in such proximity to the great American machines that the contrast will be striking, will be the original machine in which Wilbur and Orville Wright made the first flight in the world's history in a heavier-than-air machine. Near this old Wright plane will be a copy of the original Langley plane, which, although built before the Wrights made their flight, was not flown until afterward and after Prof. Langley's death.

A remarkable feature of the exposition will be the accessories exhibit. Although the aircraft industry is very young it has already called into being a vast system of subsidiary manufactories. There are some 35,000 parts in a De Haviland aeroplane and many of these parts come to the aeroplane plants complete and ready for installation. Just as the accessory and parts people form an essential part of the automobile business, so they are entering into the production of aeroplanes and lighter-than-air craft. Bearings, veneer, glue, fabrics, castings, instruments, wire, leather and rubber form the elements of the aeroplane and their importance will increase as the plane is devoted more generally to commercial purposes. The accessory exhibits will occupy extensive space on the elevated platform of the Garden, in the exhibition hall and in the armory.

Many of the planes proposed by the Navy will be exhibited by the various people who produced them, so that the naval flying section of the exhibit will include mainly the experimental NC-1, the fifty-passenger flying boat; and a model of a rigid dirigible. There will also be a display from the Naval Aircraft Factory at League Island, showing an F-5 boat hull, with wing and tail sections.

The naval instrument section will include an accelerometer, air speed meters, balloonet guage, bilge pumps, communication helmets, fire extinguishers, hydrogen leak detectors, incidence indicators, inclinometers, instrument board, K. B. board box, manometers, oxygen respirators and breathers, pigeon carrier, safety belts, tension meter, turn indicator, etc.

The Navy type of rotary motor will be shown in the motor section of the Bureau of Steam Engineering Exhibit, and unique and foreign types of radiators will be included, as well as radiator shutters, oil and water heaters for use in cold water, self-starter for Liberty engines, combination electric and hand starter for Liberty engines, radio equipment, electric equipment, lamps, intercommunicating sets, airship type of running lights, electric heated clothing, recognition lights, and compass receiver.

The Bureau of Ordnance will show aerial bombs of various types, wind vane and ring sights, pistols and ammunition, the full ordnance of guns and equipment to be carried on the NC-1..

The Bureau of Navigation has available for shipment to New York an interesting collection of instruments, including the following: Taylor altimeter, 20,000 feet; Tagliabue altimeter, 25,000 feet; keyless clock, Waltham clock, electric clock, various types of compasses, barograph, pocket aneroid, atlas chart board, course and distance finder, bearing plate, navigation notebook, deviation cards, statoscope, goggles and life jackets.

The Navy has just received from abroad a consignment of carrier pigeons with remarkable war records. These pigeons will form another part of the exhibit.

As a distinct feature, the Navy also plans a motion picture exhibition, having just completed reels showing flights over Washington and along the Atlantic Coast.

Dayton Wright Honeymoon Aeroplane On Display

An aeroplane named "The Honeymoon Express" by the Dayton Wright Aeroplane Company, its designer and maker, has been brought to New York for display at the Aero Show at Madison Square Garden. It contains three seats, one for the pilot and two for the bride and groom. It is lavishly upholstered, and contains a heating apparatus for the comfort of the passengers. A telephone between passengers and pilot and a wind shield are other features of the plane.

Aeroplane Speeds Business in Iowa

Sheldon, Iowa.—Lieutenant Donaldson, late of the Army Air Service, is the first aviator on record to use an aeroplane for commercial purposes in Iowa. Lieutenant Donaldson carried a passenger from Nulford to Orange City, Iowa, and return, stopping over at Sheldon on his return trip to deliver certain important documents.

New Reserve Military Aviators

In accordance with recommendations from the Training Section, the following named officers are rated as Reserve Military Aviators: 2nd Lieut. Leland B. Bass, A. S. A.; 1st Lieut. A. L. Dade, Jr., A. S. A.; 2nd Lieut John M. Martin, A. S. A.; Captain Wilbur F. Wright, A. S. A.; Capt. Charles G. Eidson, A. S. A.; 1st Lieut. Hilton M. Patton, A. S. A.; 2nd Lieut. Clyde V. Finter, A. S. A.; Capt. C. A. Miller, A. S. A.

New Commandant at Great Lakes

Chicago, Ill.—Rear Admiral Frederick D. Bassett, formerly commander of the U. S. S. Utah, today became commandant of the Great Lakes Naval Training Station, succeeding Captain Archibald Scales, who leaves to assume the superintendency of the Naval Academy at Annapolis. Captain Scales had been at the Great Lakes only two months.

Debarkation Hospitals for Air Service

Washington, D. C.—The Surgeon-General's Office announces that sick and wounded men of the Air Service flying personnel, on arrival at ports of debarkation will be sent to Army General Hospital No. 2 at Fort McHenry, Baltimore, Md. Those already convalescent are sent to the Air Service Depot, Garden City, L. I.

Flying personnel patients arriving at General Hospitals already convalescent will be sent to the Military Convalescent Hospital, Cooperstown, N. Y., or to the Air Service Depot at Garden City.

General Mitchell Decorated

Paris, France.—Brigadier-General William Mitchell, Chief of Air Service, 3rd Army of Occupation, was named a commander in the French Legion of Honor.

Government Aeroplane Factory for Fisher Body Corp.

Detroit.—Fisher Body Corp. is now endeavoring to lease or purchase the aeroplane factory adjoining its plant, built by the Government for aircraft production. Federal officials are now in the city. An inventory and survey of the plant is under way, and the matter will probably come to a head in the course of a few days.

Detroit-Pittsburgh Aeroplane Express Route Advocated

Detroit.—Automobile and other automotive industrial companies are asked to guarantee sufficient business to permit the establishment of an aeroplane express route between Detroit and Pittsburgh this spring. The Detroit and Pittsburgh Boards of Commerce have endorsed a plan submitted by Lieutenant B. Vernon, Flying Field, Philadelphia, for the immediate establishment of such a line, providing sufficient business can be secured. Lieutenant Vernon proposes to operate two planes, one to fly from Detroit to Pittsburgh and the other from Pittsburgh to Detroit, stopping at all intermediate cities. Discounting time required to make principal stops, a machine leaving Detroit at 10.30 a. m. will reach Pittsburgh at 3.30 p. m.

The proposed air express company will carry express for $1.78 a pound, subject to a 40 per cent discount if a satisfactory amount is sent at one time.

Development of the Castor Oil Industry

With the entrance of the United States in the war, the sudden enormous increase in demand for castor oil for aeroplane motors proved to be a serious problem. However, the co-operation of the Signal Corps, the Department of Agriculture and the Export Bureau of the War Trade Board in the solution of this problem and the energetic campaign that was conducted was a thorough success. Captain H. L. Scaife went into the work of persuading farmers to produce this crop and his success can be judged by the fact that 108,000 acres were planted in the United States with additional acreages in Central America, Cuba, Haiti, and San Domingo. The estimated crop is 2,000,000 gallons.

Mr. W. W. Stockberger, Department of Agriculture expert on castor beans, estimated that the California yield per acre ranged from 30 to 40 bushels, while the Middle West was only able to produce from 15 to 25 bushels per acre.

The zeal of the California land owning public not only resulted in large castor oil plantations on the ranches, but also in back-yard cultivation in the cities.

Castor oil is necessary on the high speed rotary motors, such as used on combat and advanced training planes but is not required for the Liberty Motor.

Personal Par

Elbert Warford, who has been in the aviation service, has returned to his former position as advertising manager of the Seattle branch of the B. F. Goodrich Rubber Company.

The reconstructed De Havilland Biplane with Rolls-Royce engine, that is being used by Premier Lloyd George and Bonar Law, for their journeys to the Paris Peace Conference from London

Director of Sales Office Being Organized in War Department

Washington, D. C., January 29th.—A Board of Sales Review under the direction of C. W. Hare, and his assistant E. C. Morse, has been selected, each member of which is an expert in some particular class of materials. Lieutenant-Colonel A. Le Mar will be in charge of machine tools, metal and wood railway and power machinery; Major W. M. Crunden, building material and supplies; Captain Fred Glover, motor trucks, motor cars, motorcycles, and supplies and parts for same; Mr. L. H. Hartman, quartermaster supplies, gasolene, barbed wire, etc.; Mr. G. F. Woods, real estate; Captain A. L. Mercer, raw materials, minerals, metals, chemicals, etc.; and an additional member for all types of ordnance and munitions.

New Jersey to Prohibit Aerial Hunting

Trenton, N. J.—A law is being recommended to the New Jersey State Legislature prohibiting hunting from aeroplanes. In arguing in favor of the proposal, Mr. Robertson S. Ward, of the Fish and Game Commission pointed out that a large number of ducks have been slaughtered by airmen on Long Island, New York, without their having been gathered from the surface of the water after being shot.

Whale Hunting by Aeroplane

San Diego, California.—Lieut. James McCullough, attached to the army's aerial gunnery school at Ream Field, near San Diego, Cal., recently shot and killed a small whale with the machine gun of his aeroplane off Imperial Beach. Several of the army airmen saw a whale spouting about two miles offshore and made for it. Lieut. McCullough soon swooped down near the animal and let loose a stream of bullets at it. The broad back of the whale looked like a sieve when he had finished firing. Residents of Imperial Beach towed the whale ashore.

Film Company Seeks Transatlantic Photo Rights

New York.—It was recently learned here that a large film company is planning to raise $100,000 as a prize to the first flyer to cross from England to the United States. The method that will be employed to raise this sum will be to select one hundred firms, each representative of a particular industry and to photograph for $1,000 its plant, its officers, and product in the same multiple reel film depicting the preparations of the flight, its start, the flight and the landing. It was said that some of the money had already been pledged.

Arrival of Doctors by Aeroplane Prevents Critical Situation

Norfolk, Va.—Owing to the poor transportation facilities, the population of the isolated districts of Manteo, Ocracoke, and near-by communities, had been unable to secure outside assistance when a large proportion of the population became victims of influenza. The situation was brought to the attention of the Federal authorities. Two doctors and a quantity of medical supplies were dispatched by means of a naval aeroplane. Many families were found with every member ill, and only remedies available were home-made medicines. The arrival of the doctors was a complete surprise and the situation was greatly improved before their departure.

Wolf Hunt by Aeroplane

Indianapolis, Ind.—Aeroplanes will direct the movement of hunters in a wolf hunt to be held in the White River district. Wolves have been observed here recently, and it is anticipated that the aviators will make it possible to make a large haul.

Civilians May Wear Chevrons

Washington, D. C.—There are no regulations covering the wearing of Chevrons after entry into civilian life and it is understood that the War Department has no objection to the wearing of gold, silver, blue, or red chevrons after return to civilian apparel.

Lewis Gun Mounting Improved at Taliafero Field

Under the direction of Lieut. H. C. Parish, the experimental department of this field has recently perfected and constructed a double Lewis Aircraft gun.

Two Lewis guns are mounted side by side about ten inches apart and so aligned that the lines of sight converge at two hundred yards range. The sights are attached to the right gun and a double trigger mechanism is operated from the left gun. A universal jointed rod connects the two trigger mechanisms and when the guns are properly timed both can be fired by pressing the trigger of the left gun. Either gun can be operated singly simply by removing the connection of the rod to the trigger mechanism of that particular gun.

Each gun carries a large Lewis magazine and an extra large deflector bag. Parts of each gun are interchangeable and ample clearance is provided for clearing jambs or changing parts.

The French government has been using a design of double Lewis gun, but in their design the framework connecting the two guns is very heavy and bulky. Also there is no mechanism by which both triggers can be pulled from one single stock. Their arrangement was simply two separate guns on a single mounting, while this is two guns which operate as one. Full details of the design and construction of this new improvement have been furnished the navy of this country for its approval and use.

Other worthy inventions and improvements are the electrically operated automatic firing mechanism on the Marlin Aircraft Gun, which is synchronized with the propeller. Also the stationary mounted Lewis gun, which is mounted on the center section of the upper wing and is operated in a similar manner to the fixed camera gun which we now use.

Naval Radio for Aircraft Makes Great Strides In War

The report of Rear-Admiral Robert S. Griffin, U. S. N., Chief of the Bureau of Steam Engineering, states that radio telegraphic communication from planes in flight to land stations is possible for a distance of 200 miles; communication from land to plane is practicable for distances up to 50 miles. Improvements in the vacuum tube for transmitting has made radio telephony possible from plane to shore for sixty miles and inter-communication for fifteen miles. The Bureau has provided and maintained 4,000 radio stations on naval merchant vessels.

Vedrines Plans Around-the-World Flight

In an interview following his feat of landing on a Paris roof, Jules Vedrines outlined his plan for an around-the-world flight to a group of newspaper men. Given the necessary financial backing, he declared that it would be possible to accomplish this feat in three months, allowing for stoppages.

"I should begin with a tour of Africa, then go East to India. From India I should fly via the Straits Settlement to Australia; there is a pretty big jump thereabout, but I believe I could manage it. Back from Australia I should fly by the same way and on to Japan, then via Siberia and across the Behring Strait to Alaska." From there Vedrines would fly to San Francisco across the United States to New York, thence to Newfoundland, across the Atlantic to Ireland.

Newarker Is President of Aerial Photographers

Sergeant Henry Van Arsdale, of 44 Avon avenue, Newark, is president of the U. S. A. Aerial Photographers Association, which was recently formed at the aerial photograph school at Rochester, N. Y., with a charter membership of 400. Sergeant Van Arsdale is an instructor at the school. He attended Newark Academy and was graduated from Princeton in 1910. He then attended the New York Law School. He was inducted into service by Local Board No. 9 of this city.

It is expected that nearly all of the aerial photographers now in the army will become members of the new association, which will hold yearly meetings.

Honorably Discharged from Air Service

The following officers have been honorably discharged from the Service of the United States: 1st Lieut. Earl Z. Giblon, 2nd Lieut. Oliver M. Smart, Capt. Lee A. Christy, 2nd Lieut. Fred E. Kunkel, Major James Barnes, Capt. Ord Preston, 2nd Lieut. Sumner B. Emerson, 1st Lieut. Augustus J. P. Gallagher, Capt. Roderick Tower, 2nd Lieut. Levin Rank, 1st Lieut. John Levi Clark, 1st Lieut. Ned V. Tanner, 1st Lieut. Quilla Coleman Duke, Capt. Percy J. Ebbott, 2nd Lieut. Jesse I. Memefee, Col. E. Lester Jones, Capt. Carl A. Miller, Capt. John H. McCawley, 1st Lieut. Edmunds Easters, 1st Lieut. William D. Irvine, Capt. Donald G. Keeble, 2nd Lieut. Victor B. Caldwell, 1st Lieut. Van Winkle Todd, 2nd Lieut. James Moore.

Payne Field Has Many Possibilities

West Point, Miss.—The record of Payne Field as an aviation instruction school, under the command of Lieut.-Col. Jack W. Heard, is an excellent one. According to a recent statement this field has a record of eight hours in the air for each and every machine attached to the field.

This is partly due to the natural conditions, the terrain in the locality being most adaptable to aviation. The field is situated in a natural field of open country four thousand miles square. Aviators assigned here have frequently remarked about the absence of air pockets and bumps, which makes it an ideal flying country. The weather conditions are good.

It was from this field that flying officer Harry Weddington made a cross country flight of 4,000 miles, visiting twelve aviation fields. On Thanksgiving Day, in charge of the same officer, 100 ships, directed by wireless, spelled the word "Victory" in the air. The formation extended over one mile and flew for ten miles.

The O.E.C. 80 H.P. Le Rhone Training Scout, designed and built by the Ordnance Engineering Corporation

National Advisory Committee for Aeronautics Gets New Quarters

Washington, D. C.—The National Advisory Committee for Aeronautics announces the removal of its offices from the fourth wing, second floor, building "D", 4th Street and Missouri Avenue, N. W., Washington, D. C., to the fourth wing, third floor, same building.

In the future the official address of the Committee to which all communications should be addressed will be as follows, and all parties concerned in addressing mail or other matter to the Committee are requested to take notice of, and use this form:

National Advisory Committee for Aeronautics,
D-433, 4th Street & Missouri Ave., N. W.,
Washington, D. C.

Colonel Nugent H. Slaughter in Charge of Radiophone Development

Washington, D. C.—Following the announcement that the War Department had developed a successful radiophone for aircraft, the names of those connected with the development were made public.

As early as August 1910, Colonel Culver (then a lieutenant) began experiments on radio telegraph sets for aircraft. In October of that year, at the International Aviators Tournament at Belmont Park, Colonel Culver conceived the idea of voice-commanded aerial manoeuvring. In 1915 Colonel Culver was detailed to San Diego for working out a series of radio sets for aeroplanes, including design of reception apparatus. Upon the outbreak of the war, General George O. Squier, Chief Signal Officer of the Army, called into conference leading radio engineers, including Dr. F. B. Jewett, of the Western Electric Company; Colonel Rees, of the R. F. C., and Colonel Culver. As a result of this conference, the Radio Development Section was organized, Lieutenant-Colonel Nugent H. Slaughter being made officer-in-charge. The organization which Colonel Slaughter built up designed and brought to the point of production the numerous types of radio equipment used by the Army. Capt. G. Francis Gray directed the research work conducted by manufacturers and others outside of the Signal Corps. The energetic work of these officers resulted in the design of the most advanced type of radio equipment.

Fourth Annual Speed Boat Regatta Will Have Sham Air Battle

Miami, Florida.—Fifty aeroplanes through the courtesy of the commanders of the Naval Aviation Schools at Miami and Key West will perform stunts for the amusement of the crowds. Silver cups will be awarded to the aviators performing the most spectacular stunts.

A mock air battle will be a feature of the program. Two flights of aviators from the Marine Corps School will meet in an exhioition engagement over the race-course. Several seaplane races for silver cups are also on the program.

G. J. Kluyskens Moves to Larger Quarters

G. J. Kluyskens, Inc., importer of foreign aircraft motors, has moved from his former offices to larger and more centrally located quarters at 220 Broadway, New York City.

1,000 Feet Jump from Seaplane in a Parachute

Mr. Leslie L. Irving made a parachute jump from a seaplane recently at Rockaway Beach, L. I., from an altitude of 1,000 feet. The seaplane was in full power flight. The parachute, designed and developed by Mr. Irving, opened very rapidly and was fully spread before a drop of 50 feet had been attained. The descent thereafter continued at a rate of only 7 miles an hour. An excellent feature of the Irving Parachute is that its course can be guided during descent.. The style of harness with which the chute is equipped is so designed as to permit immediate release of the parachute upon reaching the ground, thus preventing the parachute from dragging the aviator along the ground in a high wind.

Major Biddle Addresses National Geographic Society

Washington, D. C.—Members of the National Geographic Society heard just how America's intrepid aviators drove the enemy back into his own country and helped bring the war to a victorious close, when Maj. Charles J. Biddle, one of America's foremost "aces" spoke before that organization in the New Masonic Auditorium.

Maj. Gen. William L. Kenly, chief of the air service of the United States Army, introduced Maj. Biddle and in doing so told something of the administration of America's flying corps from Washington during the country's participation in the great war.

Official motion pictures just received from France of the foremost Yank fliers in action over the lines were shown for the first time with Maj. Biddle's lecture. These pictures show Capt. Rickenbacker, leading American "ace" doing "stunts" high up in the clouds over the trenches and the official decoration of these flying men on the field in France with the distinguished service cross, the highest honor received by Americans in the war.

Speaking of the employment of parachutes as a means of reducing aviation casualties, Major Biddle said:

"I am not aware that any of the entente allies' air forces used the parachute except in connection with observation balloons, but there are numerous instances on record in which the German fliers used this means of gliding to safety from a wrecked or burning aeroplane. One of these instances I witnessed. On that occasion the enemy plane was a two-seater which had been put out of commission by one of our pilots. The machine went into a spin and at a height of several thousand feet the observer fell out and, of course, was instantly killed. The pilot, however, while still some distance from the ground, succeeded in jumping with his parachute and landed safely."

Work of S. A. E. in War

The record for war service of the Society of Automotive Engineers is an enviable one, its members having participated in all phases of war activity.

For several months prior to the entry of this country into the war, committees of this Society at the request of the Transportation Division of the Quartermaster Department made a careful study of military truck specifications, starting with a draft originally prepared by that department. When this work was taken over by the Motor Transport Corps, members of the Society were called upon to do a large proportion of the work.

At the request of the Secretary of the Navy, the Society appointed two of its members, who had been presidents of the Society, members of the Naval Consulting Board, an organization which rendered very valuable service to the Nation. One of these past presidents later became chairman of the Aircraft Board, a group of patriotic men of affairs, which though they labored under great difficulties performed service of unquestioned value to the Government, among other things arranging for the design and production of the Liberty engine.

Both of the engineers who figured prominently in the design of the Liberty engine were members of the Society, one of them being an officer of the Society at the time the work was undertaken.

Another and very logical outcome of S. A. E. work in aircraft standardization matters was the creation of an International Aircraft Standards Board, the chairman and most of its members, so far as this country was concerned, being members of the Society whose experience had been gained in serving on the S. A. E. Standards Committee.

The International Aircraft Standards Board made a trip to Europe early in 1917, and laid the foundation for international cooperation in aircraft standardization matters. This resulted in inestimable good to the Allies as well as to this country.

Similar cooperation in aircraft standardization matters was brought about with the Navy Department, with which most cordial and beneficial relations existed.

Other members of the Society serving both on the committees of the National Advisory Committee for Aeronautics and in cooperation with the National Bureau of Standards, helped to bring about research work of no little importance in the Government program. One result of this work was the design and establishment at the Bureau of Standards of so-called altitude laboratories, in which it was possible to submit engines to test under the low pressure and temperature conditions encountered in actual flight. Laboratories of this character were a novelty in the field of engineering and were the means of securing much data of great value.

The aeronautic division of the Standards Committee of the Society held many important sessions during the war and adopted many standards for aircraft parts and materials which were later of great benefit to the Government in the preparation of aircraft specifications. This work was done at a time when few appreciated, as did the Society with its long experience in standardization matters, the need and value of such work without which production in quantity is beset with the greatest difficulties, if not impossible.

The Sunstedt Trans-Atlantic Cruiser being assembled. It is equipped with two Hall-Scott motors

The AIRCRAFT TRADE REVIEW

Curtiss Sales Force On Peace Basis

With the ending of the war, most of America's big industrial concerns, whose efforts have been bent toward the defeat of the Hun, are now being transferred back upon a peace footing. This transitions is, necessarily, a slow process, owing to the suddenness of the break down of the German military system, but already many firms are operating on the same basis as before the war.

The Curtiss Aeroplane and Motor Corporation, which has been dominant in the development of aeronautics in the U. S. since the earliest days of experimentation, and which, at the entrance of America into the struggle, was equipped to assist in the air program adopted here, is now rapidly getting back to a peace basis. It has made plans for continued dominance in the commercial field which has been opened up through the achievements of the aeroplane during the war.

John N. Willys, president of the Curtiss Corporation, who has been most successful in the creation of new markets, has defined plans for a sales campaign, which will place Curtiss products in all parts of the world.

The sales office has been opened at 52 Vanderbilt Avenue, New York City, and will be under the supervision of J. P. Davies, who has been in the air service since the beginning of the war. Mr. Davies, in addition to his technical experience gained through study of aeronautics both in this country and abroad, has had wide experience in salesmanship. Previous to his enlistment, he was a successful general agent in Wisconsin for the Northwestern Mutual Life Insurance Company. After a year as instructor at Ellington Field, Texas, was sent to the fighting front in France as a representative of the government, to study night bombing in order to install a uniform course of instruction at the flying fields in America.

Associated with him will be E. H. Ballard, C. W. Webster, and J. M. Bickel, as assistant sales managers. Messrs. Ballard and Webster have been with the company for several years, and they are thoroughly familiar with Curtiss products. Mr. Bickel was formerly treasurer of the Madison, Wis., *Democrat*.

Fay L. Faurote, advertising manager, formerly located in Buffalo, has transferred his organization to Garden City and to the New York office. Associated with him will be W. D. Richardson, formerly with the Milwaukee *Sentinel*.

Personal Pars

G. Edward Barnhart has accepted the position of chief engineer in the Handley Page engineering department of the Standard Aircraft Corporation, Elizabeth, N. J.

E. K. Hill, formerly with the inspection department of the Wright-Martin Aircraft Corporation, New Brunswick, N. J., has accepted the position of mechanical draftsman for the E. J. Longyear Company, exploring engineers, Minneapolis, Minn., and builders of drills and other mining machinery.

W. H. Wilson has left the Lincoln Motor Company, Detroit, and is now with the Wright-Martin Aircraft Corporation, Long Island City, N. Y.

E. K. Hoag has been appointed engineer in the sales department of the Hyatt Roller Bearing Company, Detroit. Mr. Hoag left the company to engage in war work, having been with the engineering division of the Motor Equipment Section of the Ordnance Department.

L. M. Baker has been engaged as a special sales engineer by the Hyatt Roller Bearing Company.

Major Howard Blood, executive officer of the Aeroplane Engineering Division, Dayton, Ohio, has been transferred to the Finance Division at Detroit, Michigan.

Standard Parts Operating On Peace Basis

Cleveland, Ohio.—The Standard Parts Company has reorganized its organization on the pre-war basis with a separate general management for each plant. The executive, financial and supervisory functions will be executed through the main offices, but each plant will be put on a competitive basis.

The general managers of the various plants are as follows: Standard Welding Plant, H. H. Newsom; Perfection Spring Plant, F. F. Grimmelsman; Bock Bearing Plant, George H. Kleinert; American Axle and Cincinnati Axle Plants, producing Stan-Par Axles, D. K. Moore, with headquarters in Cleveland; Canton Spring and Canton Forge Plants, J. B. Childe; Connersville Spring and Wheeling Axle Plants, E. V. Overman, with headquarters in Cincinnati; Pontiac Spring Plant, B. A. Litchfield; Flint Spring Plant, R. T. Armstrong; St. Louis Spring Plant, M. B. Champ; Perfection Heater Plant and Spring Jobbing Division, B. R. Winborn.

Lewis P. Kalb, formerly Major of design, testing, and specification division of the Motor Transport Corps, has joined the engineering department of the Standard Parts Company as assistant to the director of engineering. Mr. Kalb has been identified with the engineering forces of the Kelly-Springfield Motor Company and the Pierce Arrow Motor Company.

Mr. A. L. Watts, formerly a Captain in the specification and record section of the engineering division of the Motor Transport Corps and previously with the Pierce Arrow Motor Car Company has also joined the engineering forces of the Standard Parts Company.

Mr. Charles B. King, A. M. E., of the Signal Corps, who was entrusted with the re-designing of the French Bugatti engine, as outlined in our last and present issues. Mr. King has had entensive engineering experience

New Aeroplane Classes at the College of the City of New York

New classes in aeronautics are being started this month at the College of the City of New York. To take care of the expansion in the work in this Department, a number of courses are being added to those previously given, making a total of five courses now offered in this field. These include aeroplane mechanics, aeroplane engines, aeroplane design, aeroplane drafting and a factory inspector's course. The instruction is given in the evenings, each course lasting eight weeks.

Applicants should apply directly to the College for registration.

The College has an equipment of about $85,000 worth of aeroplanes and aeroplane engines. It has turned out over 450 students in these courses since their commencement last summer.

The courses last eight weeks and a registration fee of $10 is asked.

Aeroplane Gets Oil Man There First

Dallas, Texas.—An aeroplane was recently used by officers of two oil companies in a race to arrive first at a newly discovered oil field.

Many oilmen are considering the use of aeroplanes as a rapid means of transportation between the various Texas oil holdings. The favorable terrain and the fact that so many thousand aviators have learned to fly in Texas has brought the general population of this part of the United States, perhaps more than any other, to consider the aeroplanes for practical use.

Addressing Mail to A. E. F.

Attention has been called to the fact that many persons are addressing mail to members of the American Expeditionary Forces since the signing of the armistice to the French cities or towns where troops are stationed. Mail so addressed cannot be delivered under the jurisdiction of the United States at the three-cent rate and is returned to sender unless five-cent postage is provided.

Large quantities of mail have been lost in this manner.

Curtiss Motors Make Excellent Record

When Ensign T. E. Maythem of the Navy air service established what is thought to be a new world's record for time spent in continuous flight he used a Navy dirigible driven by a Curtiss OXX motor. The record, which has been allowed officially, is 40 hours 48 minutes in the air.

The flight was made on December 24-26 and Ensign Maythem was accompanied by Chief Carpenter's Mate J. H. Collier. The course covered 691 miles, exclusive of thirteen hours of exhibition flying at Key West, Tampa, Cape Sable and Palm Beach.

A thirty-two-hour endurance flight was made in another Navy dirigible on November 23-25, the Curtiss OXX motor being used. Previous to this flight the motor had 90 hours in the air without overhauling. During the flight the motor was not stopped at any time, oil being supplied from a three-gallon auxiliary tank and additional water being found unnecessary.

The dirigible carried full equipment, totalling 832 pounds. This included extra oil, gasoline, clothing, sea-anchor, life-belts, camera, radio apparatus, light and batteries.

Martin Bomber in 450-Mile Flight

Glenn Martin Bomber Number 4, arrived at Bolling Field, Anacostia, D. C., February 6th, from Cleveland. The entire trip, via Baltimore amounting to practically 450 miles air travel, was made in two hours and fifty-eight minutes. This is the second machine of this type delivered to the Division of Military Aeronautics by the Glenn Martin Company. It will be flown to New York later in the month for exhibition in the International Aeronautical Exposition at Madison Square Garden.

The Martin Bomber was piloted by Mr. Eric Springer of the Martin Company and carried three passengers, the Chief Engineer of the Martin Company, a representative of the Post Office, and a mechanic.

Chest of Gold For U. S. "Ace"

Los Angeles, January 27.—A chest of gold for Eddie Rickenbacker, the Los Angeles race driver who became the American "ace" of aces in France, is proposed to the Pacific Aero Club, in a letter received today from Miss Katherine Stinson, the aviatrix. Miss Stinson is in Paris. She accompanied her suggestion with a check for $300 as the first contribution.

"It would be a shame if Rickenbacker was compelled to commercialize the glory he has attained in the skies of France," says Miss Stinson.

"The war has developed two great American heroes—Gen. Pershing and Eddie Rickenbacker. Now that the war is ended, promoters by the score are attempting to contract with Rickenbacker to give exhibition flights in the United States. I know that he does not wish to commercialize his glory.

"May I not suggest that the automobile people of America and others who admire him contribute to a chest of gold for Rickenbacker that will eliminate any possibility of his flying against his wishes."

Hon. Albert S. Burleson, Postmaster General
Hon. Otto Praeger, Second Assistant Postmaster General

Alaska Seeks Aerial Mail

Juneau, Alaska.—Governor Thomas Riggs, Jr., of Alaska is making a strong effort in co-operation with the Post Office Department to secure bids for carrying mail by aeroplane from Valdez to Fairbanks.

The substitution of aerial mail transportation for the dog and sled will result in saving of many days in the delivery of mail, and make possible much more frequent delivery. Some districts now have only one delivery per month owing to the difficulties of travel, but the use of aeroplanes will obviate many of these.

Brazil Authorizes Aerial Mail

Under an executive decree of October 23, 1918, Joao Teixeira Seares and Antonio Rossi are authorized to establish an Aeroplane Mail Service between Rio de Janeiro and the capitals of the different States of Brazil. The service is to be in operation, unless the time is extended, within a period of two years. In addition to mails and parcels, if aviation development so justifies and the Government agrees thereto, persons may also be transported.

Cuba to Have Aero Mail Service to Key West

A report from the Havana press is to the effect that a company with a large capital has been organized in New York to establish a daily mail and passenger aeroplane service between Havana and Key West, employing the Caproni machines for this purpose.

Trans-Adriatic Postal Air Service

According to *Giornale d'Italia*, a trans-Adriatic Aerial Postal Service has been established between Venice and Ancona, and Trieste, Fiume, Porenzo, Zara, and Pola. A service will be shortly established between Brindisi and Dalmatia.

Captain William F. Jones in Charge of Testing

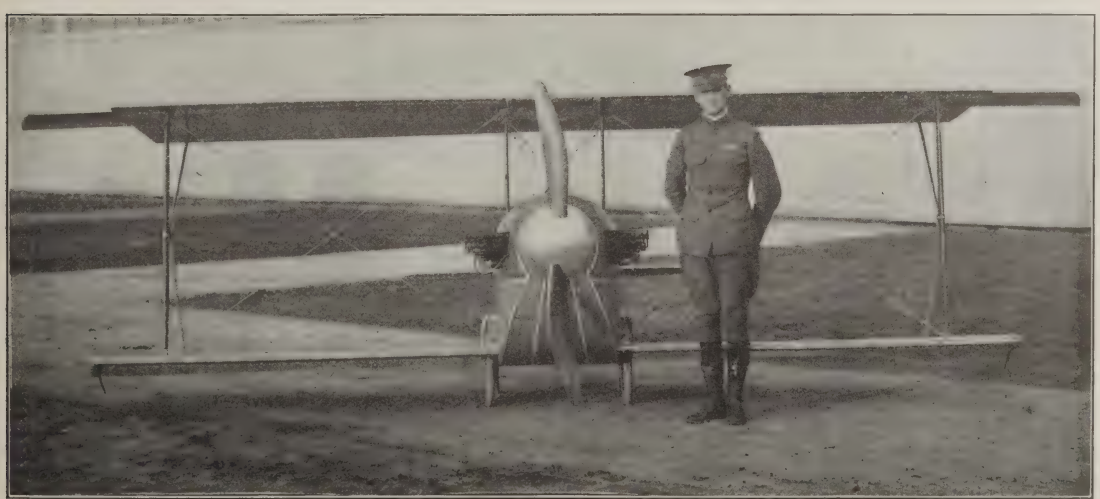
Captain William F. Jones has been the commanding officer of the Proving Section at Wilbur Wright Field for some months, and in that capacity has supervised the official tests of new types of aeroplanes upon which the War Department desired full information as to defects and possibilities.

In the performance of this duty Captain Jones was the first American aviator to pilot "The Langley," the first American-built Handley Page machine. Captain Jones is a pioneer in the testing of parachute devices, and under his direction official tests of such devices submitted by the Technical Section of the Division of Military Aeronautics were conducted.

Among the speedy flights which Captain Jones has made was one from Detroit, Michigan, to Dayton, Ohio, a distance of 212 miles, in 84 minutes, flying a new La Pere fighting plane.

Captain H. M. Horton, Air-Radio Pioneer An R. M. A.

Riverside, California.—Captain H. M. Horton, now stationed at March Field, has been rated a Reserve Military Aviator. Captain March worked with Colonel Culver at San Diego in the early radio experiments on aircraft, which were started in 1910.



Captain E. L. Ryerson, Second Lieutenant R. G. Elbert and Second Lieutenant D. I. Henderson have been rated Reserve Military Aviators.

Gasoline and Kerosene Carburetors, By Victor W. Page

A New Up-to-Date Book on Modern Carburetion Practice. This is a simple, comprehensive and authoritative treatise for practical men on the basic principles pertaining to carburetion, explaining how liquid fuels are vaporized for operating all types of internal combustion engines. All leading types of carburetors are described in detail, special attention being given to the forms devised to the use of the cheaper fuels, such as kerosene. Carburetion troubles, fuel system troubles, carburetor repairs and installation, electric primers and economizers, hot spot manifolds and all modern carburetor developments are considered in a thorough manner. Methods of adjusting all types of carburetors are fully discussed as well as suggestions for securing maximum fuel economy and obtaining highest engine power. This book is invaluable to repairmen, students and motorists. The drawings showing carburetor construction are made from accurate engineering designs and show all parts of late types of carburetors.

Table of contents: Chapter 1, Liquid Fuel suitable for power; Chapter 2, Liquid Fuel supply methods; Chapter 3, Carburetors Action and Construction; Chapter 4, Modern Gasoline Carburetors; Chapter 5, Kerosene Carburetors; Chapter 6, Manifolds and Carburetors Installation; Chapter 7, Carburetor Faults, Location and Remedies.

This book can be purchased at The Aeronautic Library, Inc., 299 Madison Ave., N. Y. C., at the price of $1.65 postpaid.

Recent picture of the Martin K-III Scout, designed by Captain Jas. V. Martin, and comprising some of the special Martin features

THE BELLANCA 35 H. P. BIPLANE

THE light passenger-carrying Bellanca biplane has been designed to answer the requisites of quick get away, fast climb, and high speed, and to have at the same time light weight, the ability to glide at a flat angle, and low flying speed to insure a great degree of safety in landing. To these qualities are added the item of moderate cost and ease of maintenance, high-grade construction and the possibility of rapidly assembling and dissembling.

The inventor had in mind the idea of presenting a machine which would be of universal use for popular flying as well as for training. Careful attention was given to all details as dictated by the latest research and accepted good practice. That such things have been attained the demonstrations of its performances seem to bear out.

The machine was tested out at Central Park, Long Island, just about a year ago by Pilot Arthur Heinrich. On his first flight he released the controls when an altitude of 1,000 feet was reached. Perfect stability and high climb were observed. The throttle was full open. Without touching the controls, the throttle was retarded to diminish the power about 50 per cent and the machine proceeded in straight horizontal flight. With the engine shut off the machine quietly disposed itself to a flat glide.

Other tests of the machine's speed show that with full power, it is capable of 85 m.p.h., and by throttling the engine the speed can be reduced to 34 m.p.h. The value of this performance will be better realized when it is understood that the Bleriot and Deperdussin monoplanes of similar horse power have a speed range of 40 to 46 and 40 to 48 m.p.h., respectively. Favorable comparison will also be found with a number of modern machines, both European and American, with 100 h.p. or more, which make an average speed of 70 to 80 m.p.h.

In climb tests the Bellanca biplane ascended to 3300 feet in 10 minutes and 4600 feet in 14 minutes, with the engine throttled down to 1080 r.p.m., equal to 18 h.p.

With the engine turning at 1080 r.p.m. the machine made a speed of 69½ m.p.h. in three consecutive half-mile flights at a height of 15 feet from the ground. The speed mentioned was the average for the three flights. With the engine increased to 1,200 r.p.m., equal to 24 h.p., the climb of the machine increased to 530 feet per minute and the horizontal speed was 76 m.p.m. The climb was measured by means of a barograph and aneroid.

In testing the gliding quality, the pilot began a glide from an altitude of 4,600 feet at a distance of about ten miles from the starting point. With the engine shut off the field was reached and passed, and it was necessary to turn back and glide against the wind toward the field, adding two miles to the distance traversed. In this maneuver a time of 8 minutes and 5 seconds elapsed before the ground was touched. In this glide the machine was favored by a wind of 6 to 7 m.p.h. The incidence angle indicator showed that the machine was gliding at an angle of 5 degrees, which is equal to a ratio of 1 to 11.5.

The above test shows that in case of a forced landing from an altitude of 4,600 feet, the pilot will have ample time to select a landing place within a diameter of 24 miles.

General Description

Best selected white ash is used for the principal parts of wings, fuselage, landing gear, etc.

Brazing and welding have been eliminated wherever possible. Care has been observed to avoid the piercing of longerons and other vital members.

Safety Factor

The factor of safety of lift stresses on the beams of upper and lower wings is 16, and the factor of drift stresses is 14. In the body and landing gear the safety factor of the weakest point is 12.

Field tests have shown a high safety factor under difficult conditions. Even in snow 14 inches deep, the machine never met with difficulty in leaving the ground nor in landing. In diving and even in tail spinning tests, the machine was quick to recover itself, confirming the strength of sustaining surfaces.

Assembling Facility

In actual tests, the machine was dissembled in 15 minutes and reassembled ready to fly in 20 minutes. This item is expediated by the employment of a special turnbuckle, which can be loosed and detached without losing the adjustment of tension, so that a simple movement restores the attachment of the cable with its original adjustment.

General Specifications

Span, upper plane	26'-0"
Span, lower plane	20'-6"
Chord, upper plane	4'-0"
Chord, lower plane	2'-4"
Total area	150 sq. ft.
Length overall	17'-7"
Weight, machine empty	400 lbs.
Useful load	375 lbs.

Performances

		(*Miles per hour*)
Maximum Speed, Light	35 H. P.	85
	24 H. P.	76
	18 H. P.	70
Minimum Speed		34

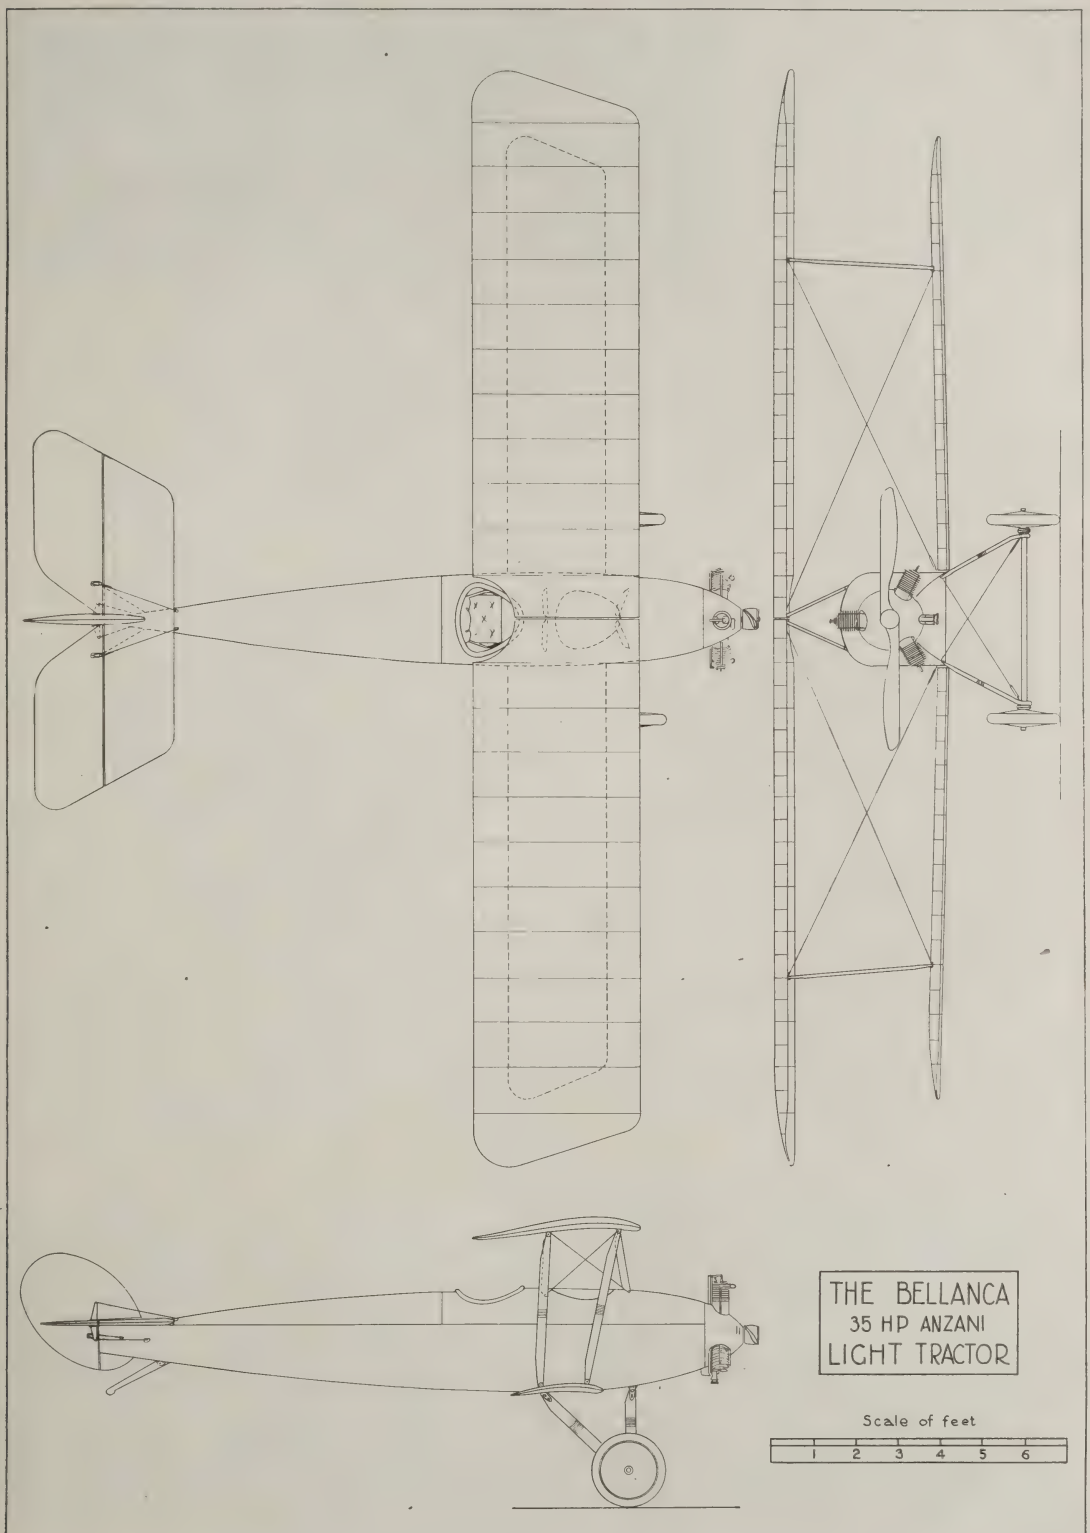
		(*Feet per min.*)
Maximum Climbing Speed	35 H. P.	820
	24 H. P.	530
	18 H. P.	330
Gliding Angle		1 to 11.5
Min. H. P. required for horizontal flight		6

Main Planes

The dynamical stability of the planes is almost the same as the Eiffel 32. It is most suited to high speed because of its very small drift at small angles of incidence, and because of the structural advantages afforded by the section.

Spars are of ash, having a safety factor of 14. Struts between planes are of streamline section of constant depth for two-thirds their length. Ends taper to the strut fittings.

Controls



Lateral and longitudinal balance is operated by stick control. The rudder is balanced; it is operated by the foot bar.

Lateral control is obtained by warping the

McLaughlin

(*Continued from page* 118)

wings, and its effect is so immediate as to require but a slight movement of the stick.

Fuselage

The fuselage is of good streamline form. Its wooden frame is of box-girder construction, braced by cables from the pilot's cockpit forward and with wire from the same cockpit rearward. The nose is covered with aluminium, a round door in one side giving access to the engine. The remainder is covered with linen, doped and varnished. The front deck is of veneer, linen covered. The body tapers to a vertical strut edge at the rear, on which the rudder is hinged. No bolts pass through the fuselage spars, a simple and light fitting making this possible. In front of the pilot is a dash, on which are found oil sights, clock, aneroid, inclinometer, and incidence angle indicator.

Landing Gear

The chassis is of the ordinary V type, each V consisting of two ash laminated streamline struts, joined together by steel and aluminium plates. Rubber shock absorbers bind the axle to the struts.

Tail Group

The empennage group is composed of a non-lifting fixed stabilizer, to which is fastened the elevator flaps.

The attachment of the stabilizer is such that it is easily detached by removing four cotter pins.

The rudder is of oval shape and is of sufficient area to insure complete control in handling the machine on the ground.

The Bellanca Biplane, which makes a speed of 85 M.P.H. with a 35 H.P. Anzani Engine

Engine Group

An ir cooled 3 cylinder Anzani Y type 35 H. P. is used. Its weight is 120 lbs. Propeller 6'-7" in diameter and 5'-9" pitch. The engine is so attached as to form with the rest of the body a perfect streamline form with low head resistance.

Only part of the cylinders are exposed, which are efficaciously cooled by such a flow of air as obtained by a speed of 85 M. P. H.

To ascertain the complete cooling of the engine, repeated and accurate tests were performed. The engine was first tested on the ground, and after five minutes' running, it was already losing 15% of its initial H. P. This loss was increasing as the engine continued to work.

On the contrary when the machine was flying, such power loss was almost completely eliminated, for after from 40 to 60 minutes of flight, no over-heating was observed.

A convincing proof of the mentioned condition has been given by measuring the rate of climb, for it was shown by the barographic charts that the rate of climb remains almost uniform for the first 5,000 feet.

Even the speed tests confirmed the results previously obtained, for the speed at the beginning and at the end of trials was similar.

CITED FOR DISTINGUISHED SERVICE

THE commander in chief, in the name of the President, has awarded the distinguished service cross to the following named officers and soldiers for the acts of extraordinary heroism set forth after their names:

First Lieut. Robert Lindsay, 139th Aero Squadron. For extraordinary heroism in action near Bantheville, France, October 27, 1918. In company with two other planes, Lieut. Lindsay attacked three enemy flanes (Fokker type) at an altitude of 3,000 meters, and after a sharp fight brought down one of them. While engaged with the two remaining machines, eight more planes (Fokker type) came at him from straight ahead. He flew straight through their formation, gained an advantageous position, and brought down another plane before he withdrew from the combat. Home address, N. H. Lindsay, mother, Madison, N. C.

First Lieut. James O. Beane, 22d Aero Squadron. For extraordinary heroism in action near Bantheville, France, October 29, 1918. When Lieut. Beane's patrol was attacked by eight planes (Fokker type) he dived into their midst in order to divert their attention from the other machines of his group and shot down one of the Fokkers in flames. Four other Fokkers then joined in the battle, one of which was also destroyed by this officer. Home address, Wilfred Wheeler, 81 Ludbury Road, Concord, Mass.

First Lieut. Josiah Pegues, 95th Aero Squadron. For extraordinary heroism in action near Duns-sur-Meuse, France, November 5, 1918. On account of heavy clouds and mist, Lieut. Peques became detached from his formation. While endeavoring to find it he came upon eight hostile planes, which were maneuvering to attack four of our planes. With great courage and skill he passed through the formation and, attacking its leader, dispersed the formation, preventing further attack. Home address, S. F. Pegues, father, 643 Woodlawn Avenue, Chicago, Ill.

Capt. Reed Chambers, 94th Aero Squadron. For extraordinary heroism in action near the Bois de la Cote, Lemont, France, October 21, 1918. Capt. Chambers is awarded a bar, to be worn with the distinguished service cross awarded him November 8, 1918. While on a voluntary patrol, Capt. Chambers encountered five enemy planes (Fokker type) harrassing our Infantry at an altitude of 300 meters. Attacking them without hesitation, he shot down two of them and drove off the others. Home address, J. S. Chambers, father, Fort Huachuca, Ariz.

First Lieut. Shelden V. Clarke, Balloon Section. For extraordinary heroism in action near of enemy territory on August 28 and September 26, 1918. While making a general surveillance of enemy territory on August 23 and September 26, 1918, Lieut. Clarke was attacked by enemy planes. On both occasions he remained at his post and directed the fire by telephone until his balloon had been set on fire. On August 28 he assisted a passenger to descend and did not jump himself until the other's parachute had opened. On both occasions he re-ascended as soon as another balloon could be obtained. Home address, Virgin A. Clarke, mother, 39 East Third Street, Williamsport, Pa.

First Lieut. Harlow P. Neibling, Field Artillery. For repeated acts of extraordinary heroism in action at Brouville, France, September 2, 1918, and near Fort Dummar, France, September 26, 1918. While Lieut. Neibling was making an aerial reconnaissance from a balloon, he was repeatedly attacked by enemy planes, two of which dived at the balloon and opened fire with incendiary bullets. With great coolness he fired at one of them with his pistol and took a picture of the plane with his camera. When the balloon took fire he was forced to jump, but he took two more pictures on the way down in spite of being fired upon. He re-ascended as soon as a new balloon could be inflated. On September 26 this officer was again attacked while conducting a reglage, but hanging from the basket with one arm he fired his pistol at one of the enemy planes and jumped only when his balloon burst into flames. He immediately continued his mission in another balloon. Home address, Mrs. Elizabeth Neo, mother, 1819 Lyndale Avenue, South Minneapolis, Minn.

First Lieut. Sumner Sewall, 15th Aero Squadron. For repeated acts of extraordinary heroism in action near Menil-la-Tour, France, June 3, 1918, and near Landres-St. Georges, France, October 13, 1918. On June 3 Lieut. Sewall with two other pilots attacked a formation of six hostile planes. Though his companions were forced to withdraw because of jammed guns, he continued in the fight for 15 minutes and succeeded in sending one of his adversaries down in flames. On October 18, while on a voluntary patrol, this officer saw an American observation plane being attacked by a German machine (Fokker type), accompanied by eight other hostile planes. He immediately attacked and destroyed the Fokker and was in turn attacked by the other eight planes. By skillful manoeuvering he evaded them and escorted the observation plane back to our lines. Home address, W. D. Sewall, father 1142 Washington Street, Bath, Me.

First Lieut. George C. Carroll. For extraordinary heroism in action near Fort Dumarr, France, September 26, 1918. Lieut. Carroll had ascended in a balloon to a height of 1 kilometer on a reglage mission, when he was attacked by enemy planes; but he refused to leave his post and fired on the planes with his pistol while incendiary bullets were striking his basket and balloon. He was finally forced to jump when his balloon burst into flames, but he reascended as soon as a new balloon could be inflated. On three occasions Lieut. Carroll also gave proof of exceptional courage by remaining in his balloon in the face of aeroplane attacks, jumping only when his balloon took fire and immediately re-ascending when a new balloon could be inflated. Home address, Harry S. Carroll, father, Garrett, Ind.

First Lieut. Harold H. George, 139th Aero Squadron. For extraordinary heroism in action near Bantheville, France, October 27, 1918. Lieut. George displayed great courage in attacking a formation of four enemy planes (Fokker type), destroying two of them in a terrific fight and driving the other two back to their own territory. Home address, William H. George, brother, 210 East Tenth Street, New York, N. Y.

First Lieut. Percy Rivington Pyne, 103d Aero Pursuit Squadron. For extraordinary heroism in action near Dun-sur-Meuse, France, October 23, 1918. While protecting three planes on a photographic mission, Lieut. Pyne attacked and drove off five enemy machines (Fokker type). Later another German formation of seven (Fokker type) was encountered, but despite the odds Lieut. Pyne swung up into the midst of the enemy and scattered them, diving on one of the Fokkers and sending it crashing to the ground. Home address, Percy R. Pyne, father, 680 Park Avenue, New York City.

First Lieut. George R. Nixon, Field Artillery. For repeated acts of extraordinary heroism in action near Domevre-en-Haye, France, August 29, 1918, and near Malan-court, France, September 28, 1918. On August 28 Lieut. Nixon was locating active enemy batteries from his balloon and was attacked several times by enemy planes, but refused to descend until one had set fire to the balloon. On September 28, while he was on a reglage mission, five enemy planes fired at him. He remained in the basket until the balloon was a mass of flames, and one of the enemy aviators followed him to the ground, firing at him. Despite his narrow escape, he immediately re-ascended. Home address, Mrs. George E. Nixon, wife, 748 South Harvard Boulevard, Los Angeles, Cal.

First Lieut. William Thomas Ponder, Aviation Section, 103d Aero Pursuit Squadron. For extraordinary heroism in action near Fontaines, France, October 23, 1918. Having been separated from his patrol, Lieut. Ponder observed and went to the assistance of an allied plane which was being attacked by 30 of the enemy. Lieut. Ponder destroyed one enemy plane and so demoralized the remaining that both he and his comrade were able to return to their lines. Home address, W. P. Ponder, father, Mangum, Okla.

First Lieut. John J. Quinn, 139th Aero Squadron. For extraordinary heroism in action near Bantheville, France, October 23, 1918. While patrolling the lines, Lieut. Quinn, with one other pilot, sighted and attacked four enemy machines (Fokker type). Several additional enemy planes joined the first four, and, notwithstanding his great odds, he sent one machine crashing to the earth. Motor trouble forced him to drive straight through the enemy formation, and although followed and his machine badly damaged he was able to outmaneuver and escape from his adversaries. Home address, August N. J. Quinn, father, 407 Post Office Building, Philadelphia, Pa.

DOUGLAS AUTOMATIC AEROPLANE IGNITION INTERRUPTER

THIS instrument, designed to increase the safety factor in flying, is a product of the war period. It is unique in its particular field and in its functioning is said to have met every requirement.

The Interrupter is an invention of Theodore Douglas, President of The Duplex Engine Governor Company, Inc., of Brooklyn, N. Y., and was developed by him under the auspices of the National Advisory Committee for Aeronautics. Facilities for the development were furnished by the Navy and Army at various Air Stations.

The function of the instrument is to automatically interrupt the engine ignition, thereby stopping the power development of the engine, in the event of the propeller breaking, or other similar breakage resulting in a seriously unbalanced condition of the power plant.

In flying, other than under war conditions, the danger of such breakages is fortunately not serious, though it is always present. With certain types of machines the danger is greater than with others. Under war conditions on the other hand such breakages, accidental or from gun-fire, are very frequent and in a large percentage of cases end fatally for the pilot.

The tendency of a tractor plane, in the event of its propeller breaking, is to go into a dive, and of a pusher plane to go into a tail-stall. Under such conditions either type of machine is apt to pass into a spin as a result of the unbroken propeller blade tending to swing the machine around a neutral, or pivot, point between the centre of pressure of the unbroken blade and the centre of torque. Other factors may increase or lessen this influence, and the engine may or may not go overboard as a result of the unbalanced torque reaction.

The resulting intense vibration is apt to break a gasoline line, and, consequent upon the continuance of the flame of combustion exhausting into the gasoline-charged atmosphere, be followed by fire. Sometimes the most perfect mental and physical coordination on the part of the pilot fail to prevent this, since the brain and hand can seldom act quick enough, as many thoroughly understood accidents of this nature attest. This manual limitation will be better realized when we consider that the time interval per revolution for aeroplane engines, assuming full throttle, varies from one twenty-third to one twenty-seventh of a second. Even under peace conditions some of our best pilots have been unable to prevent fatal crashes following such mishaps. This is particularly true at the present time with the high powered engines, high engine speeds, four bladed propellers, and the generally high stresses employed.

The interrupter supplements the action of the pilot in such instances, and through practically instantaneous action interrupts the power development, thereby confining the danger to the initial breakage. Such a breakage is seldom serious in itself. The danger lies in the unbalanced power development which follows, and the consequent injuries to the plane may range from a weakening of the general structure without showing visible fracture, through broken bearers, crankcase, crankshaft, gasoline line, etc., to a fatal crash. How important, then, it is to localize the danger through limiting the breakage to the initial incident—the propeller. The monetary cost and danger from such accidents would not be great if the danger stopped with the propeller. It is the consequent breakages which count, and particularly the overstraining of the general structure.

The interrupter is thought to be particularly desirable on twin-engine machines, as such an accident happening to one engine would cause the good engine to tend to suddenly swing the machine around and probably into a spin. On such machines the interrupter may be so installed as to instantly cut out both engines, thus maintaining an approximately normal flying position. The pilot then has the alternative of making a landing with dead engines, or of switching off his damaged engine and continuing his flying with his good engine and reduced speed.

In the equipment of the blimps the instrument would find another important application, as it would tend to reduce the fire risk following propeller breakages, as the propeller fragments are apt to puncture the gas bag.

The Design

As to the elements of the design of the instrument, these are extremely simple and may be briefly described as consisting of a suitably pivoted metal bar, so mounted as to swing in a plane transverse to the axis of rotation of the propeller. By means of tensions springs "2"-"2", the free movement of this bar is confined, under normal aeroplane operating conditions, to a very limited arc in its plane of movement. The amplitude of this movement is determined by the weight of the bar, the intensity and frequency of the transverse vibrations of the engine, and the opposing strength of the springs confining it. The extended end of the trigger "3" is constantly pressed toward the floor of the instrument by the compression spring "4", and is designed to engage the latch "5". On the under side of the trigger "3" there is an inclined surface "6", by which the trigger is raised. A ball-pointed hardened steel screw is fitted into the bar directly beneath the trigger, and designed to engage an inclined surface and thus to lift the trigger when the swing of the bar is sufficient. When the trigger is lifted the latch "5", held under tension by the spring "7", is released and moves out of engagement with the trigger. The cam "8" is for the resetting of the latch through rotating it back into position by means of the push button "10" from the outside of the instrument.

The compression spring "9", presenting an unbalanced force, is designed to prevent the bar from disengaging the latch "5" as a result of cylinder misses coinciding with bad vibration periods of the engine, etc., thus increasing the amplitude of the swing of the bar through synchronism, or from lateral shocks to which the plane may be subjected in landing. An intense oscillating shock transverse to the axis of the engine, such as an unbalanced engine-propeler torque reaction resulting from the breaking of a propeller at speed, are the types of shock from which the instrument is designed to operate, and to which it will immediately respond. Under such conditions the bar will swing through its full amplitude, raise the trigger, which releases the latch, and thus interrupt the ignition through grounding the magnetos. From the interrupter terminals "11" and "12" wires are connected to the grounding terminals of the magnetos, and from the terminal "13" of the interrupter a wire is connected to the engine ground. On the disengagement of the latch "5" a triple contact is made between the interrupter terminals "11", "12" and "13".

Provision is made for testing by the pilot before each flight, of the operation of the interrupter. Such a test can be conducted in ten seconds. The handle "14" which projects through a slot in the end of the instrument is pushed gently to the left until the red spot "15" of the tell-tale, which bears a luminous cross for night flying, appears. Before the engine stops, the instrument may be re-set by pressing down on the button "10" until the red spot of the tell-tale disappears. Should the engine not stop it would indicate that either the interrupter switch is in the wrong position, or that its wiring system, etc., is defective.

A manually operated switch is provided with each instrument, by which the interrupter may be thrown into and out of the grounding circuit as desired.

Types of Interrupters

Interrupters are furnished of two general types, maker and breaker instruments, and in several models to best suit various engine and air plane conditions.

Maker-instruments, such as the one just described, are intended for magneto ignition engines, in which cases there is no flow of current through the instrument, excepting at the moment of interrupting the ignition.

Breaker-instruments are intended for Liberty engines, using the Delco system, where the flow of the current is constantly through the instrument, and where two separate current channels are provided, because of the double distributor system used on these engines. The interruption of the ignition results from breaking these channels.

Different Models

The interrupter is manufactured in five models, suiting it to the two general ignition systems employed—magneto and Liberty—and to the requirements of engine location whether on the fuselage or in the wings. All instruments are provided with shunting switches. When the engine is located in the wings, the interrupter is mounted on a weather-proof casing attached to an engine-bearer, and the shunting switch is located on the instrument board.

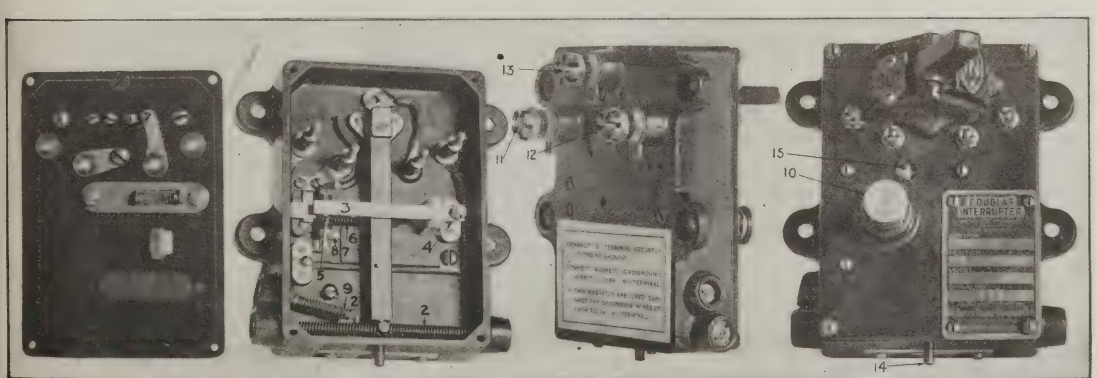
The weight of the instrument, of both types and of all models, is under ten ounces.

Its Efficiency

The point has been raised that the presence of the instrument would be apt to complicate the ignition, and particularly so on the Liberty engine. Theoretically this would seem to be so, yet practically, judging from statements of naval pilots who have been flying interrupter-equipped machines during the past six months, experience would indicate that this possibility need not be seriously considered, as during that entire period the ignition of these Liberty engines has at no time been adversely affected. The operation of the instrument has been most satisfactory in every way and has fully met all of the claims which have been made for it.

The various tests of the interrupter made by the Navy Department have shown in general the following results:

(a)—As nearly as it has been possible to determine, the instrument will operate within one complete revolution of the engine following the propeller breakage, or within a time interval of one-twenty-third of a second.



(b)—It may be depended upon to do this every time that such a breakage occurs, as shown by tests in the air and on the ground.

(c)—It will not interfere with the efficiency of the ignition system, nor has it caused complications therein of any kind.

(d)—The electrical resistance of the interrupter on Liberty engines has been determined by a representative of the Delco Company as being less than .03 to .05 ohm, representing a loss of potential in the primary current to the distributors of .33 to .55 of one per cent, a value which is entirely negligible.

The design, workmanship, and materials employed in the construction of the interrupter are of high quality. The latches and triggers of the instruments are of hardened steel heavily silver plated to minimize electrical resistance, to

The Douglas Automatic Aeroplane Interrupter

LIEUT. HAROLD H. EMMONS, CHIEF OF ENGINE PRODUCTION DEPARTMENT

LIEUTENANT HAROLD H. EMMONS, U. S. N. R. F., A. S. A. P., has been Chief of the Engine Production Department, Aircraft Production Board, since August 15, 1917, until the signing of the armistice. As such he directed the contracting and production of all the aviation engines for the Army and Navy, which totaled 95,993. These engines, together with their spare parts, called for the expenditure of upwards of $450,000,000. Of these engines 31,814 had been delivered when the activity was stopped by the termination of the War. During the month of October, 1918, Liberty 12-cylinder engines were produced and delivered into Service at the rate of over 150 per day. Of all types of Aviation engines over 200 were delivered into Service for each working day of that month. This was a greater production than was achieved by England and France combined during any month during the four years of the War. Production of engines would have reached 8,000 per month by January, 1919, and 10,000 per month by early Spring.

Just prior to entering the Service he was an active member of the law firm of Clark, Emmons, Bryant & Klein. Lieutenant Emmons up to 1917 was a leading executive in a syndicate operating factories for the manufacture of automobiles, carburetors, magnetos, stamped metal ware and parts. This, together with his experience as a member for nineteen years of the Michigan Naval Reserve, fitted him for the responsible work which he so successfully carried on for the winning of the War.

Harold H. Emmons was born in Detroit, Michigan, June 30, 1875. He was educated in the public schools of Detroit and then attended the University of Michigan. While there he was prominent in Class, Collegiate and Inter-Collegiate activities. He was a member of the board of control of athletics and played in various college athletic teams. He graduated from the Literary Department with the degree of A.B. in 1897 and from the Law Department with the degree of LL.B. in 1899.

After his graduation, Lieut. Emmons located in Detroit and began to practise law, becoming a member of the law firm of Lucking, Emmons & Helfman, in January, 1903. In May, 1913, he left the practice of law and entered commercial life as an executive in a syndicate, referred to above. In January, 1917, he became a member of the law firm of Clark, Emmons, Bryant & Klein, from which he was called into Service.

Lt. Harold H. Emmons, U. S. N. R. F., A. S. A. P.

CAPTAIN CLIVE WARMAN GIVEN D. S. O. BY KING GEORGE

CAPTAIN WARMAN, who lived in Philadelphia, is an American subject who enlisted in Princess Patricia's Canadian Light Infantry at Valcartier on September 5, 1914, as a Canadian. He went to France with the 2nd Canadian Contingent, and was invalided back to England in 1915 and discharged. He then enlisted in the Canadian Mechanical Transport as a Staff Car Driver and served in England, Scotland and Ireland. He was in Ireland during the Rebellion of 1916, stationed near Dublin, and was slightly wounded in the cheek by a Sinn Fein Bullet whilst driving near College Green, Dublin.

Upon discharge from hospital, he applied for transfer to the Royal Flying Corps with a Commission. He was gazetted on 18th August 1916 and went to Oxford and Salisbury Plain for instruction as a Flying Officer.

Whilst training he was given leave to proceed home for three months, returning in February 1917 to complete his training. The medical authorities would not then categorize him for General Service in the Field, with the result that he spent April and May of that year flying in Scotland.

Early in June, 1917, Lieut. Warman was passed by the medical boards as Fit General Service, and immediately proceeded to France, where he was posted to a scout squadron of the Royal Flying Corps in the Field.

He immediately commenced to distinguish himself and within a few weeks was recommended for the Military Cross.

His special hobby was the German Albatross Scout aeroplane and practically all of his victims were machines of that type.

Both distinctions were gained by this officer whilst he was a Second Lieutenant, which greatly adds to their value.

Capt. Warman has up to date accounted for twenty-two Boche Aeroplanes in Flanders (five two-seaters and seventeen scouts).

Capt. Clive Warman, of Philadelphia, has won every military honor that the British Government bestows on airmen

He was flying the French Spad aeroplane fitted with Hispano-Suiza engine of the type used by the two great French Ace of Aces, Capt. Guynemyer and Lieut. Fonck.

One of Capt. Warman's victims was brought down after his Bickers machine gun had jammed and could not be fired. He dived for the Boche aeroplane at a speed which the indicator could not register (an Albatross D.5. enemy aeroplane) until in its endeavors to get away also by diving the enemy broke to pieces in the air.

On another occasion this officer was harassing enemy troops in the trenches with his machine gun when a 9-inch high explosive shell hit the right hand top plane (wing) and exploded, peppering the tail and fuselage with big holes. Instead of immediately landing his machine, which was the safest thing to do, this officer brought the Spad back to his own aerodrome, himself unhurt.

When a Boche machine came over one morning from the enemy lines at dawn and commenced harassing the British troops round Zillebeke Lake, Capt. Warman went up and shot it down. During this fight he was operating the gas lever when a bullet took it clean out of his hands, only bruising his fingers. He did not break off the fight however until successful, as the engine controls were adjusted to keep the gas levers full open if broken.

When he was eventually severely wounded by an explosive bullet in the shoulder joint during the course of an air fight in which the patrol became outnumbered twelve to three, this gallant officer flew his Spad machine back to his own aerodrome, a distance of some fourteen miles and landed the machine. He was found in his seat unconscious.

Capt. Warman's career as a fighting pilot is not finished. He is now with Col. Bishop, V.C., and will be in the Canadian Air Force on its return.

VALUE OF PLYWOOD IN AEROPLANE FUSELAGE CONSTRUCTION

By LIEUTENANT STEFANO D'AMICO, Italian Aviation Mission

RECENTLY aeroplane construction has undergone some very radical changes, in part due to the exigencies caused by the war, in part to the natural tendency to make a more and more organic machine out of the aeroplane, by employing in its design the same fundamental principles which guide the design of modern mechanical devices.

Often these two conditions have coincided so as to expedite the ultimate result.

Of all the parts of the aeroplane, the fuselage has undoubtedly undergone the most radical change. On the one end the development of aerodynamics and the necessity to get from the aeroplane the greatest speed coupled with the greatest mobility have changed its form and proportions, and on the other hand modern and more practical principles of construction have completely altered its make-up.

Until recently, the fuselage in all aeroplanes consisted of a

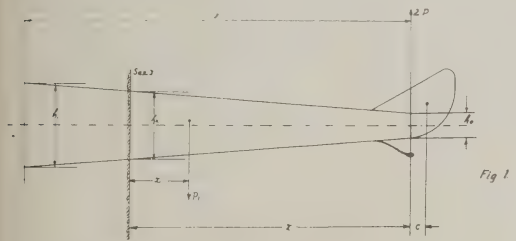

Fig 1

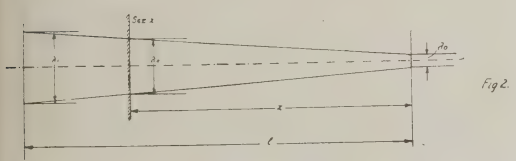

Fig 2.

frame suitable to withstand the stress and this was then covered with linen properly varnished.

The frame consisted of four longerons, running lengthwise of the fuselage with struts and steel wires latticing in both planes, vertical and horizontal, so as to divide it into panels.

The joints of the struts to the longerons were metallic fittings and the proper tension in the latticing was obtained by the use of turnbuckles.

The solid resulting by this method is capable of withstanding the stresses imposed from all sides but is a complicated structure, since it is made up of a large number of parts, has a great many wire connections, and must be frequently adjusted to the proper shape by giving the wires the proper tension.

The fuselage, because of the frequent landing, is subjected to violent dynamic stresses causing a stretching in the tension wires, a disarrangement of the whole structure, as well as a stretching of the linen covering. The elements also influence to a great extent the stretching of the covering and this impairs to a large degree the aerodynamic property of the machine.

The war then has developed it to such an extent, that while the fuselage has forfeited a little the advantage in weight, the machine has gained in life and efficiency.

At any rate, the abandoning of such a construction was desirable because of the ever-increasing scarcity of metal fittings of alloy steel, as well as for the excessive cost and the lack of labor which is felt more each day.

The use of plywood, which had already been used in large quantity in the construction of hydroaeroplane boats, appeared to be very appropriate since it eliminated a great many of the disadvantages enumerated.

In as much as the only advantage of the old type was its lightness, all the builders tried very hard to make the best use possible of the material in order to eliminate this disadvantage which, in some cases, is considerable.

In its most common form the modern fuselage is made of four longerons, tied together by means of diaphragms and then covered by plywood. The shearing stresses are taken care of by stiffening the outside covering with ribs of wood.

The transverse stiffness is attained by means of transverse diaphragms in the rear while in the front, where this is not possible, since the passengers have to be accommodated as well as the tanks, motors, etc., this is done in special way for each case, utilizing to the best advantage the space resulting in distributing the various parts of the plane. The plywood is made to resist the moments due to deflection and principally shearing stresses. In this way the material is used to its full extent and its strength utilized to the best advantage. Therefore, since the material is used to its full value, the construction becomes light.

The maximum strain on the fuselage comes on it when the tail skid strikes the ground. The maximum reaction will nat-

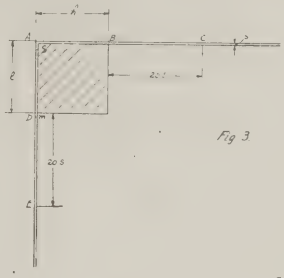

Fig 3

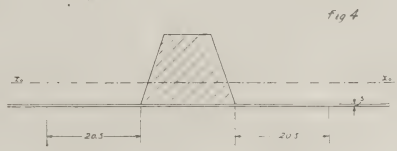

Fig 4

urally depend on the total load P, which comes on it at this point and in computing, it is customary to consider this as double; that is $2P$. (Fig. 1 and Fig. 2.)

Therefore, at the section X distant from the point where the load may be considered as applied the moment.

$$> Mx = {}_2P.X$$

From this moment must be deducted the moment due to own weight of the fuselage so that the resulting expression will be

$$M'x = 2Px - P'x.$$

In its vertical direction the fuselage suffers a *deflecting moment* due to the compound load coming on the rudder.

If this force be denoted by P'' then $Mx'' = P''(x + c)$ in which C is the distance from the axis of the tail and the center of pressure of the surface which makes up the rudder.

Considering the ordinary quadrangular form of fuselage, the distance Hx between the centers of gravity of the upper and lower longeron of the section Wx of the longerons may be considered variable and following the linear law. So that:

$$hx = ho + \alpha x;\ \alpha = \frac{> h_1 - ho}{l};\ \left[\frac{I}{y}\right]_1 = 2Wx\ [ho + \alpha x]$$

Also in the horizontal section the distance λx between the centers of gravity of the sections of the longerons may be considered in the same way as varying with straight line law.

Therefore in the same way we would have

$$\lambda x = \lambda o + \beta x;\ \beta = \frac{> \lambda_1 - \lambda o}{l};\ \left[\frac{I}{y}\right]_2 = 2\ Wx\ [\lambda o + \beta x]$$

Therefore at the longeron, with the greatest stress we will have the following united stress

$$\delta o = \delta_1 + \delta_2 = \frac{M'x}{2\ Wx\ [ho + \alpha x]} + \frac{M''x}{2\ Wx\ [\lambda o + \beta x]}$$

THE KING-BUGATTI AVIATION MOTOR

By G. DOUGLAS WARDROP, M.S.A.E., A.S.M.E.

(*Continued from last week*)

Carburetion

Four specially designed Miller carburetors are used (Fig. 41) each supplying one block of four cylinders through separate water jacketed manifolds (Fig. 42). They are set low so that gravity feed may be used and all four are identical, there being no rights or lefts.

The throttle valve is of the barrel type, the axis of all valves being parallel with the center line of the engine, the two carburetors on each side of the engine being operated by one shaft which is connected to the valves at each end through adjustable couplings. The shafts on the two sides of the engine are connected so that all four valves move in unison, the valve opening being synchronized by means of the adjustable couplings.

Gasoline from the tank enters the carburetor through the elbow (Fig. 41), passing through the strainer B-16941, thence into the float chamber, flowing out through the four 5/32" holes in the lower end of the needle valve seat.

When the gasoline reaches the proper level the rising of the cylindrical brass float lowers the needle valve onto its seat, thus stopping the flow. From the float chamber the gasoline enters the lower 3/16" hole in jet holder. There are seven of these jets, drill sizes being as follows: No. 76, which is the idling jet, No. 76, No. 75, No. 71, No. 68, No. 57, No. 53. These jets progressively come into action as the throttle is opened.

Gasoline is drawn into the jet through the small hole in the bottom of the threaded end, mixing with a certain amount of air sucked in through the four holes drilled in the barrel of the jet just above the threaded portion. This air is taken from the outside through the upper 3/16" hole in jet holder and passes down around the outside of the jet to the four holes mentioned above. The major portion of the air enters the carburetor through the lower end of the venturi, which is 3" in diameter, passes up around the jet bar holder, combining above this with the rich mixture from the jets to form the proper mixture for combustion.

Assembly of the altitude valve is shown on drawing (Fig. 43). This valve operates by turning the lever which is attached to the altitude control valve. This valve has two openings in its seat which when in the open position register with two similar openings in the stationary cover, thus making two free passages to the outer air, the size of this passage being governed by the position of the lever.

There are four outlets (Fig. 43), one of which connects to each of the four elbows, opening directly into the top of the float chamber. The float chamber is always in direct connection with the venturi through a 5/64" drilled hole opening into the venturi about ¼" above the jet holder and into the float chamber well above the gasoline level. Opening the altitude control valve decreases the vacuum in the float chamber thus increasing the flow of gasoline through the jets.

Ignition System

Ignition is by four Dixie 800 magnetos, two on each side of the engine, driven from the vertical camshaft driving shaft by bevel gearing as shown on drawing Fig. 44. All magnetos turn clockwise.

Two Titan A C spark plugs are used per cylinder located in the side of the combustion chamber.

The rear magneto on the right hand side supplies current to the rear plug in each of the eight left hand cylinders, the front magneto on the right hand side supplying current to front plug in each of the eight right hand cylinders.

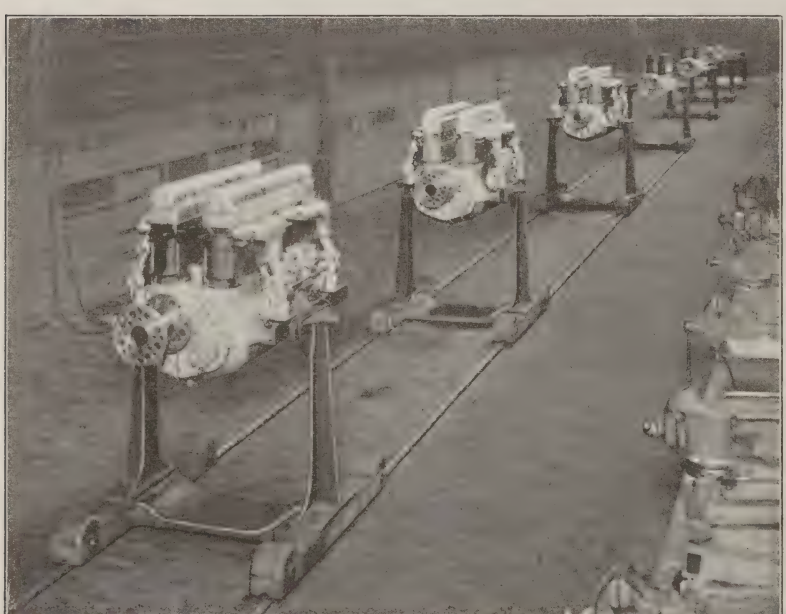
The same arrangement is followed with the magnetos on the left hand side so that the two magnetos on either side will fire all sixteen cylinders.

Magnetos are set for a maximum advance of 38°.

The bevel gear on the magneto shaft, Fig. 44, is fitted on a taper with a key. The gear has eight keyways, six spaced 48°, one spaced 42° and one spaced 30°. This in combination with the gear teeth allows the magneto to be set within 1½° on the crankshaft.

The magneto advance and retard mechanism is shown in Fig. 45. Gear B-16042 meshes with the gears on the magneto shafts. This gear has four internal spiral grooves sliding over splines on the sleeve which is keyed to the driving shaft but may be moved along the shaft by lever. The movement of this sleeve revolves the magneto driving gear in relation to the shaft driving gear, thus advancing or retarding the magnetos. The levers on the two sides of the engine are operated from one shaft located above the crankcase between the cylinder blocks, the connections to the levers being through adjustable yokes so that the magnetos may be synchronized.

Oiling System



Oiling is by means of pressure feed and spray. There is one pressure and one scavenging pump both of the rotary gear type. These are located at the front of the engine, driven directly from the crankshafts through a pin and slotted coupling, Figs. 46 and 47. This coupling is squared to the pump shaft, but is not pinned, thus relieving the shaft of any end driving pressure. The gears in both pumps are the same except that the scavenging pump gears have a wider face.

Oil, after passing through a strainer, is drawn from the supply tank by the pressure pump which is driven from the right hand crankshaft. This oil is forced into the pressure line running the entire length of the crankcase as indicated in Fig. 48. An adjustable pressure regulating valve is located in the crankcase front gear cover. It is of the poppet valve spring seated type and discharges the excess oil directly onto the propeller shaft driving gears. This valve is generally set so that the pressure gauge which is connected to the rear end of the main oil line in the crankcase registers about 30 lbs. This valve has holes drilled through the head so that there is always a certain amount of oil discharged onto the gears.

From the pressure line the oil passes up around the studs which hold this line in position to an oil passage cut along the top surface of the crankshaft bearing cap, see Fig. 48. For the center crankshaft bearing this oil is carried through a drilled hole as indicated in Fig. 51. These passages carry the oil to all the main crankshaft bearings. All the main crankshaft bearings and pins are hollow. Main crankshaft bearings No. 2, No. 4, No. 6 and No. 8 have a 3/16" radial hole drilled entirely thru them. All the crank pin bearings have a 3/16" radial hole drilled from the inside to the central hole. A 13/64" hole is drilled in the web both sides of main crankshaft bearings No. 2, No. 4, 6 and 8 connecting the central hole in the main and pin bearings. A copper shell is placed in these central holes and the ends spun over making an oil-tight joint. These shells are necked in the central portion so that a tubular oil space is left as indicated in Fig. 48.

Oil from the passages in the crankshaft bearing cap is forced into this tubular oil space through the 3/16" holes which register with this passage twice per revolution. From here the oil passes to the pin bearings, the leakage from these bearings being thrown on the cylinder walls and gudgeon pins, thoroughly lubricating these parts.

Four vertical holes are drilled in the crankcase web connecting with the oil passages in the crankshaft bearing cap No. 3 and No. 7. These holes register at the top of the crankcase with copper tubes which pass through the cylinder water jacket space, registering at the top of the cylinder block with four holes drilled in the webs of the crankshaft housing. These holes register with an oil groove of 3/64" radius cut entirely around camshaft bearings No. 3 and No. 8, right and left hand. A No. 35 drill hole connects the oil grooves with the interior of the hollow camshaft. Oil is thus carried under pressure to the hollow camshaft. From the hollow camshaft, the oil passes to camshaft bearings No. 1, No. 2, No. 4, No. 5, No. 6,

A series of King-Bugatti engines being made ready for Shipment

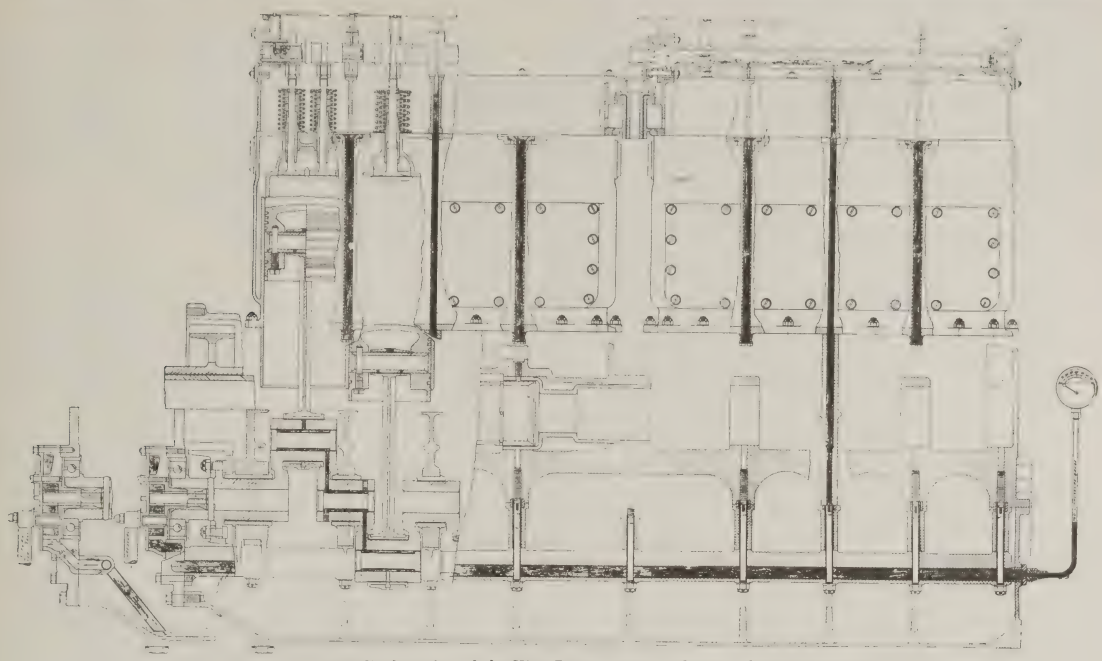


Fig. 48—Longitudinal section of the King-Bugatti engine, showing the oiling system

No. 7, No. 9 and No. 10 through a No. 35 drill hole. Camshaft bearing bushings No. 2, No. 4, No. 7 and No. 9 have a 3/32" 1/32" oil groove cut full length of the bearing surface, the drilled hole in the camshaft bearing registering with this groove once per revolution causing a small stream of oil to shoot out both sides of the bearing thoroughly lubricating the cams, valve rocher shaft, rollers and valve stems. Camshaft bearing bushings No. 5 and No. 6 have a 3/32" x 1/32" oil groove cut from ¼" of the outer edge to the inner edge, the drilled hole in the camshaft bearing registering with this groove once per revolution. Oil from this groove in the rear bearing lubricates the thrust surface of the camshaft bevel gear while the small stream from the front bearing thoroughly lubricates the camshaft and camshaft driving gears and the camshaft driving gear bearings.

A 3/16" hole is drilled in the crankcase web connecting with the oil groove in No. 6 crankshaft bearing cap and registering with a 1/16" drilled hole in the propeller shaft rear bearing bushing. This thoroughly lubricates this bearing. The oil flowing from this bearing returns to the sump by gravity.

The camshaft and magneto driving gears in the crankcase are lubricated by spray. The gearing in the camshaft housing is packed in grease.

The crankshaft and propeller shaft ball bearings are lubricated by spray.

Oil which drains to the bottom of the camshaft housing is returned by gravity to the crankcase through twelve pipes passing through the cylinder water jacket space.

Oil which drains to the front end of the sump is returned to the oil tank by the scavenging pump.

Oil which drains to the rear end of the sump is returned to the oil tank by gravity.

Cooling System

Cooling water is circulated through the engine by means of a centrifugal pump, see Fig. 49, driven from the rear end of the left hand crankshaft by a pin and coupling the same as used on the oil pump.

The cooling system from the pump inlet to the outlet elbows on the front cylinders holds four and one-quarter gallons of water.

The pump impeller is 5⅞" diameter with eight vanes, the web being drilled with eight

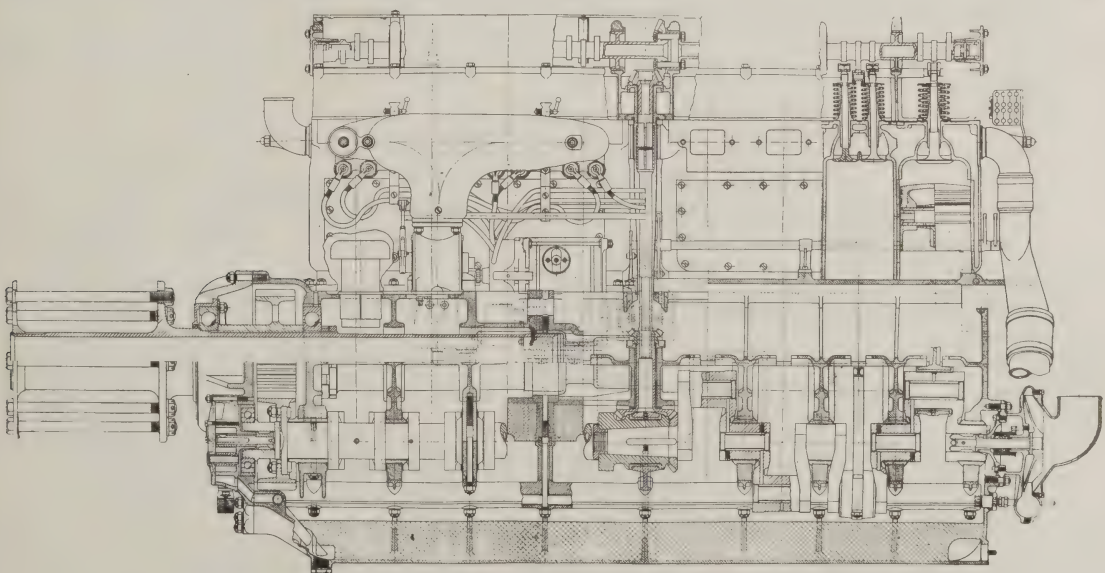

Fig. 44—The 410 H.P. King-Bugatti engine—longitudinal section

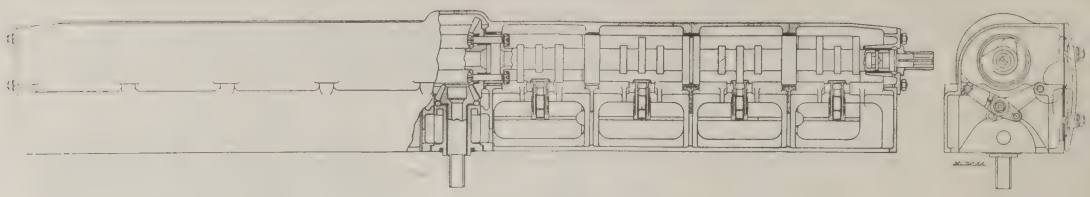

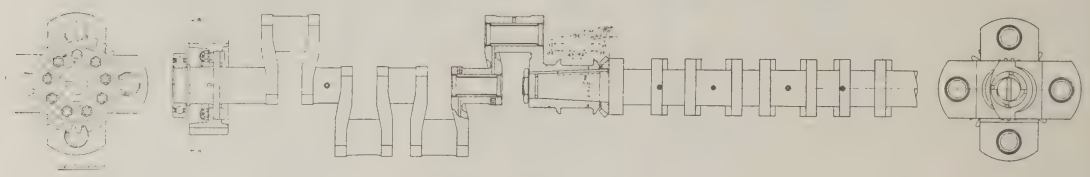

Fig. 52—Camshaft Housing Assembly—right

Crankshaft Assembly—right hand

3/8" holes on a circle of 2" diameter to equalize the water pressure.

The pump shaft is packed with a graphited asbestos rope packing, automatically held under compression by a coiled spring acting on the gland.

The pump shaft is hollow, the rear end being in direct communication with the water in the pump case. Water entering the shaft is forced out to the shaft rear bearing surface through a 1/8" hole. Any leakage of water past the asbestos packing is drained outside of the crankcase through a 5/8" cored hole in the water pump body. The front bearing on the pump shaft is lubricated by spray from the crankcase which collects on the shaft bushing support and drains down into a 1/8" hole leading to the bearing. Any oil leakage from the front end of this bearing returns to the sump, any slight leakage from the rear end of the bearing is drained outside of the crankcase with the water leakage from the rear bearing.

There is one water inlet to the pump 2 1/4" inside diameter while the single outlet is 2 3/16" diameter. Water from the pump is forced up into an aluminum pipe with one branch leading to the rear end of each of the rear cylinder blocks, water entering the cylinders at the top of the water jacket on the exhaust side. A certain amount of the water circulates thru the inlet manifold jacket, the remaining filling the cylinder water jacket space.

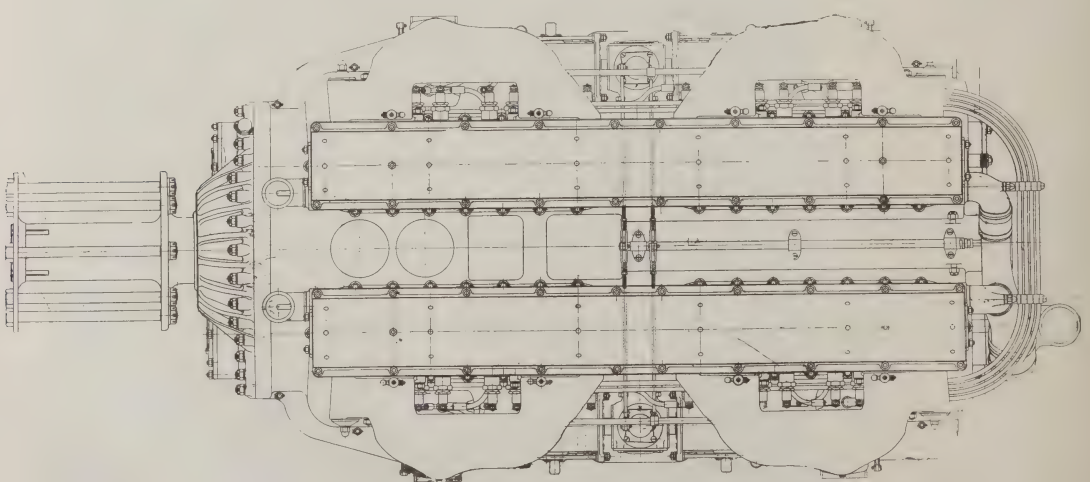
Cylinder blocks are cast with integral water jackets except the sides below the inlet and exhaust ports which are covered by an aluminum water jacket plate held in position by screws.

The construction of the water passages in the head of the cylinder is such that the valve stems and exhaust passages are very thoroughly cooled.

All four cylinder blocks are identical, the water passing from the rear to the front cylinder blocks through openings located similar to the inlet opening, leaving the front blocks through another similar opening.

Propeller Shaft

The propeller shaft is driven through a spur gear splined to the shaft meshing with a gear on the front end of each of the crankshafts, both the crankshafts turning clockwise. The propeller shaft is hollow. Provision is made for mounting a 37 m.m. cannon at the rear end of the crankcase, the barrel of the cannon passing through the hollow propeller shaft. This shaft is carried in three bearings, a ball bearing either side of the gear and a plain bearing at the rear end.



The front gear cover, the ball bearings and the gear are assembled complete as a unit before mounting in the engine. The ball bearings are No. 6219 Monarch Special, Width Hess Bright, being narrower than the standard bearing. The front bearing is mounted in the gear cover and takes all the propeller thrust as well as a certain part of the radial load. The rear bearing slides into a retainer in the crankcase, being free to move endwise, carrying radial load only. The hub of the gear acts as a spacer for the ball bearings, they being held in position on the shaft by two nuts with a locking plate between. Mounting is such that the ball bearings and gear are easily and positively assembled there being no danger of injuring the ball bearings by screwing the retaining nuts too tight.

Camshaft Drive

There are two overhead camshafts, each one running full length of the two cylinder blocks. Each shaft is made of two separate shafts joined near the center by six bolts passing through flanges on the shafts. These bolts also hold the camshaft gear in position. Each complete shaft is carried in ten plain bearings in a removable camshaft housing. The two housings are of aluminum and each one is bolted directly to the top of the cylinder blocks without the use of a gasket by twenty 1/4" studs.

The first camshaft housings had a sheet aluminum cover as indicated on Fig. 51, a later housing is made entirely of cast aluminum with a cast aluminum cover plate at the side running the entire length of the housing. See Fig. 52.

Each camshaft is operated through a bevel gear driven by a vertical shaft between the two cylinder blocks which in turn is driven by a bevel gear on the crankshaft. The gear on the crankshaft is pressed in position and in addition is held by a key. The keyway is cut in a definite position with relation to a marked tooth. The thrust of this gear is taken by the crankshaft center bearing. This gear meshes with a bevel gear which drives the vertical shaft; the thrust of the gear being taken on a bronze Babbitt lined bushing pressed into the aluminum crankcase. This gear has a long shank which acts as a bearing for the gear and has a fine external thread cut at its upper end. This upper end has a square broached hole, the hole having a definite relation to a marked tooth of the gear. The bearing for the upper end of the shank of this gear is a bronze bushing Babbitt lined pressed into the crankcase. The upper end of the bearing is cupped to form an oil well which catches the spray in the crankcase which is led to the bearing. The magneto driving shaft driving gear, see Fig. 44, is screwed into the thread at the upper end of the shank, the adjustment of the gear being obtained by means of the thread. This gear has a square broached hole the same size as the hole in the shank of the gear it is screwed to and is locked in position by dropping the camshaft driving shaft into position, this shaft having a squared section at both ends, the lower end fitting into the square hole in the magneto driving shaft driving gear and the square hole of the shank of the camshaft driv-

Number of bolts	6
Diameter of bolts	5/16"

Camshaft Housing

Material	Aluminum

Camshaft Driving Shaft

Diameter	¾"
Wall thickness	⅛"

Crankcase Upper Half

Material	Aluminum
Thickness of wall	3/16" to 5/16"
Thickness of supporting flange	⅜" to 7/16"
Center distance of motor support bolts	24¾"
Number of motor support bolts	12
Diameter of motor support bolts	⅜"
Center to center of crank shafts	10¼"
Height of case	9.055"

Crankcase Lower Half

Material	Aluminum
Thickness of wall	3/16"

Lubrication

Type	Forced feed and spray
Type of pump	Rotary Gear
Number of pumps	One pressure, one scavenging
Oil pressure	30 #

Pressure Pump

Number of teeth	7
Pitch	6
Outside diameter	1½"
Width of face	13/16"
Ratio of pump speed to crank shaft speed	1 : 1

Scavenging Pump

Number of teeth	7
Pitch	6
Outside diameter	1¼"
Width of face	1¼"
Ratio of pump speed to crank shaft speed	1 : 1

Ignition

Type	Magneto
Number	4
Make	"Dixie 800"
Firing order	1L, 7R, 5L, 4R, 3L, 8R, 7L, 2R, 4L, 6R, 8L, 1R, 2L, 5R, 6L, 3R
Number of plugs per cylinder	2
Type of plug	Titan A. C.
Advance	38°
Magneto Rotation	Clockwise

Cooling Systems

Type	Water Cooled
Pump	1 Centrifugal
Inside diameter of inlet and outlet elbow to cylinders	1½"
Number of inlets	2
Number of outlets	2
Water temperature inlet	150° F.
Water temperature outlet	160° F.

Water Pump

Material	Aluminum
Inside diameter of inlet	2¼"
Inside diameter of outlet	2 3/16"
Diameter of impeller	5⅞"
Number of blades	8
Ratio pump speed to crankshaft speed	1 : 1

Reduction Gears

Crank shaft propeller drive gear:	
Pitch diameter	5.6"
Pitch	5
Number of teeth	28
Width face	2⅛"
Diameter bolt circle	3 17/32"
Number of bolts	9
Diameter of bolts	7/16"
Propeller shaft gear:	
Pitch diameter	8.4"
Pitch	5
Number of teeth	42
Width face	2⅛"
Number of splines	48
Width of splines	.405
Height of splines	.094

Propeller Shaft

Number of bearings	3
Type of bearings	Two ball, one plain
Ball Bearings	No. 6219 Special Width, Hess-Bright
Plain bearing	Bronze babbitt lined
Diameter of bearing	3 7/16"
Length of bearing	1½"
Thickness of babbitt	1/32"
Outside diameter at gear (over splines)	3¾"
Outside diameter at rear end	3 5/16"
Outside diameter at propeller	3 31/64"
Inside diameter	2 61/64"
Diameter propeller flange	9¾"
Thickness flange	7/16"
Thickness loose flange	9/32"
Length of bearing loose flange on shaft	¾"
Diameter of bolt circle	7⅞"
Diameter of bolts	⅝"
Number of bolts	8

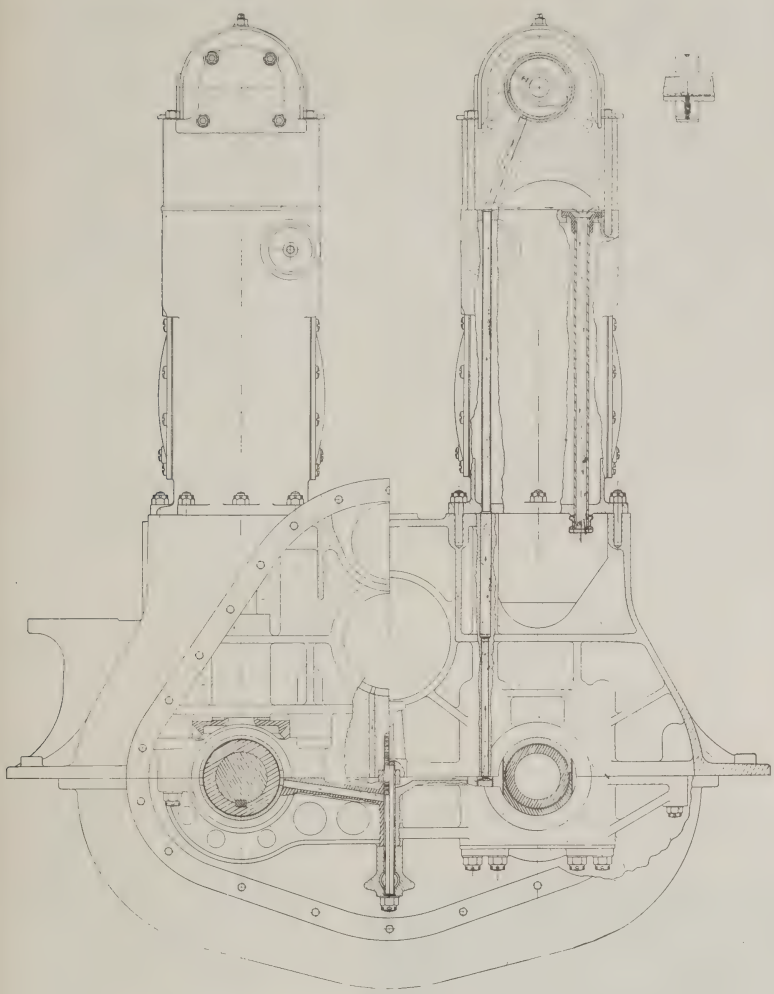
Timing Chart



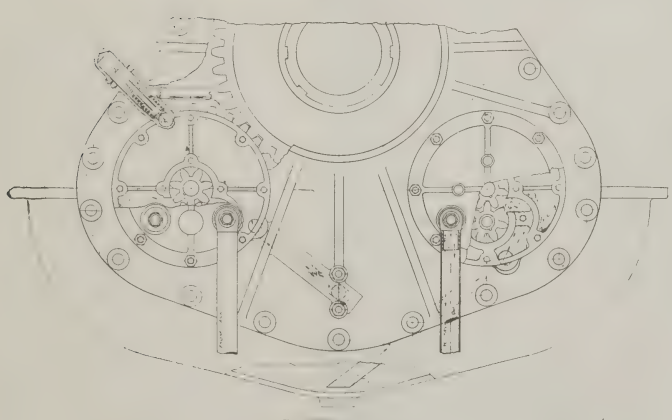


Fig. 51

Section showing oiling system—King-Bugatti Engine

ing shaft gear. The gear on the camshaft meshes with a gear having a long shank with a squared section at its lower end, the square being cut with a definite relation to a marked tooth on the gear. This gear takes a bearing in an aluminum Babbitt lined bushing which is held in position in the camshaft housing by a large flat head screw. This bushing also takes the thrust of the bevel gear. The upper end of the vertical camshaft driving shaft and the lower end of the camshaft driving gear are connected by a coupling consisting of a square piece of steel with a square broached hole fitting over these square ends.

The teeth of all the gears being marked for the meshing position they may be easily assembled in the proper positions for correct timing.

Valve Mechanism

The valves are operated by an overhead camshaft through a rocker arm. These rocker arms, Fig. 50, are pivoted on steel shafts which are slid into drilled holes along both sides of the camshaft housing as indicated in Fig. 50. There are four of these rods to each housing, each one-half the length of the housing. The ends of the rods butt together at the center, the outer ends being flush with the ends of the camshaft housing and covered by the end bearing support for the camshaft when this is bolted in position. The rods are thus prevented from moving lengthwise. They are of a tight enough fit in the drilled hole in the camshaft housing so that there is no turning motion. The outer end of each rod is tapped for a wrench to be used in withdrawing the rods from the housing.

Each rocker arm operates one valve, they are forgings and the pivot bearing of the arm on the rod in the camshaft housing is not bushed. The cam operates on the large roller, Fig. 50, which is of hardened steel taking a bearing on a hardened steel pin. This pin is held in the rocker arm by spinning the metal of the rocker arm around the beveled end of the pin as clearly shown in Fig. 50. The small roller operates directly on a cap placed over the end of the valve stem. This roller is of hardened steel and takes a bearing on a hardened steel pin the ends of which are soft and spun over into a bevel at the outer edges of the hole in the rocker arm.

The end of the valve stem has a cap slipped over it as is indicated in Fig. 44, the upper end of the cap being hardened. The proper clearance .015″ for both the inlet and exhaust valve between the end of this cap and the roller in the rocker arm is obtained by placing shims in the cap. Three different steel shims are used of .003″, .005″ and .010″ thickness, the first being octagonal, the second hexagonal and the third round, so that the different thicknesses may easily be picked out by eye.

The upper valve spring retainers have a central tapered hole, the large end of the hole being on top. The vale stems are necked and a tapered split collar is slipped into the necked portion of the stem, large end up. This taper is the same as the hole in the spring retainer. The pressure of the valve springs forces the retainer against the tapered collar which is prevented from moving by the shoulder on the valve stem thus locking the retainers into position.

Valves

The inlet and exhaust valves work in cast iron guides pressed into the cylinders. Liberal water space is provided in the cylinder head in the neighborhood of these guides so that the valve stems are well cooled.

The exhaust valve stem is hollow from the head to within a short distance of the necked portion at the upper end. The hole is closed at the head end by a short threaded plug screwed in below the surface of the valve, the recess then being filled level with the surface of the valve by welding. This closes the hole tightly and locks the plug in position. The lower end of the exhaust valve stem is of larger diameter than the upper end. Both the large and small diameters take a bearing in the valve guide as indicated on Fig. 44. At the shoulder formed by the junction of the two sizes of stem three 3/32″ holes are drilled at an angle of 30° with the axis of the stem sloping towards the head of the valve and connecting with the drilled hole in the stem. At the upper end of the stem just below the necked portion a 5/32″ hole is drilled through the wall of the stem. The movement of the valve up and down in the guide causes a pumping action, the transfer of air within the valve stem being thought to cool the steam to a certain extent. This drilling also lightens the valve.

Piston

The piston is of aluminum and has two ring grooves above the gudgeon pin. Two ⅛″ wide rings are placed in both of these grooves. The rings require a pressure of ten to twelve pounds applied on a diameter at right angles to the slot to bring the ends of the 30° slot to within .010″ of the closed position. The lower ring is beveled, being placed in the groove with the sharp edge down so that it acts as a

wipe ring forcing the oil on the down stroke into an oil groove cut just below the ring groove. The land between the bottom of the ring groove and the oil groove is 1/64" wide and it is 1/32" smaller diameter than the land above this ring groove. This forms a free passage for the oil to the oil collecting groove. Eight 3/32" holes are drilled around the piston connecting the oil groove with the interior of the piston. These holes slope down at an angle of 60° with the axis of the piston carrying the oil wiped from the cylinder wall to the interior of the piston. A slot ⅛" wide x 1/16" deep is cut from the oil groove to the gudgeon pin hole at both ends thus lubricating these bearings. Two ½" wide x 1/32" deep oil distributing grooves are cut around the piston, one about 3/16" above and one about 5/16" below the center line of the gudgeon pin.

Gudgeon Pin

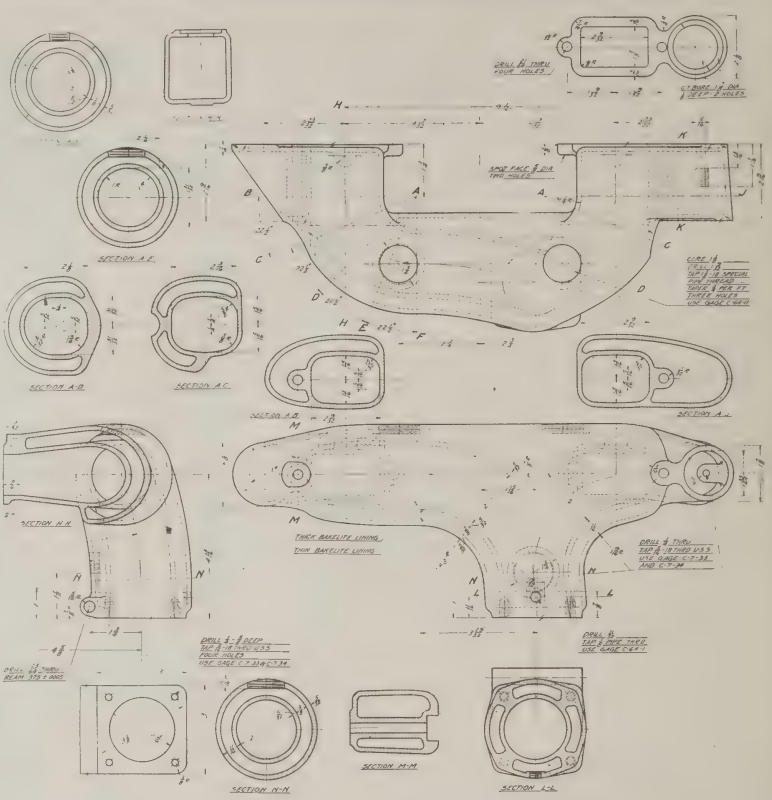
The gudgeon pin floats in both the connecting rod bushing and the piston. Bearing in the piston is directly on the aluminum. It is held from endwise motion by an aluminum plug pressed into each end. See Fig. 44. These plugs are drilled axially with a ⅜" hole, which allows a certain amount of oil from the cylinder wall to enter the hollow gudgeon pin. The ends of these plugs where they bear against the cylinder wall are turned to a spherical seat of a radius equal to the radium of the cylinder bore. In operation the gudeon pins turn more or less. Two ⅛" holes, in line, one ¾" each side of the center of the pin, are drilled through the wall of the pin. These holes when in a certain position register with an oil groove in the connecting rod bushing allowing a certain amount of oil to enter the hollowed gudgeon pin and when in the lower position allow the oil which is pocketed in the pin to run out onto the connecting rod bearing.

Connecting Rod

The connecting rod is a steel forging machined all over. It is of eye cross-section.

The small end bearing is a bronze bushing pressed in position, having one straight oil groove, 3/32" x 1/32" deep running to with ½" of the ends of the bushing. This groove is in communication with a 13/32" drilled hole in the connecting rod through a ⅛" hole. Oil collects in the pocket formed by the 13/32" hole, and is led to the bearing through the ⅛" hole.

The big end of the connecting rod is fitted with a bronze bushing which is babbitt line. This end is split at right angles to the rod on the center line of the bearing, the cap being held in position by two ⅜" chrome nickel-steel bolts. The bushing is relieved at the line by 5 grooves, 3/16" wide, about ¾" long, 3/64" deep, at the parting line cut on a 7/16" radius with a center on the parting line. The rod half of the bushing has no oil groove, the cap half has a circular oil groove entirely around it cut on the center line of the bushing and registering with the oil feed hole in the crank pin. This groove is ⅛" wide x 1/32" deep. The bushing in the cap is kept from turning by a dowel pin with an enlarged head. This head enters a countersunk hole in the cap, the small end entering the hole in the bushing when it is placed into position. This end is of such a length that it does not project through the bushing. The pin is thus locked in position and cannot drop out or rub on the shaft.



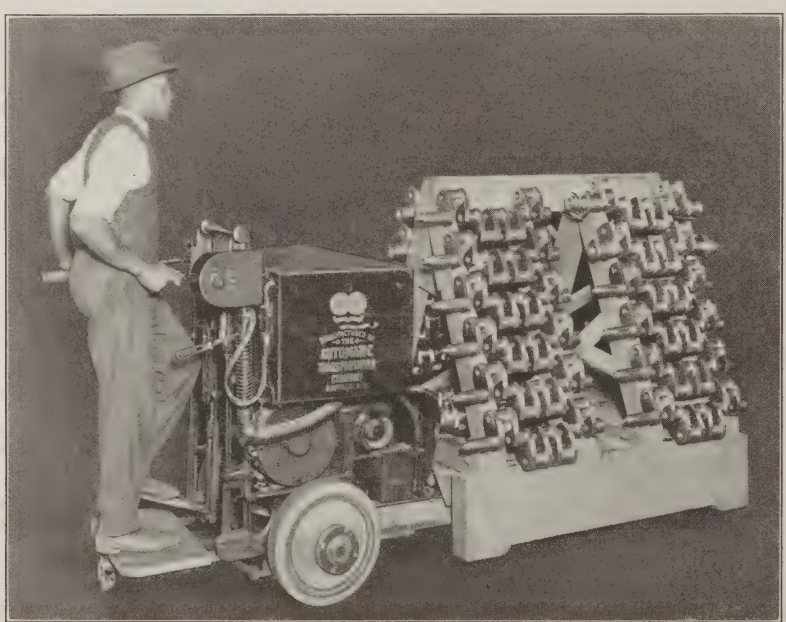


Fig. 42—Details of Gas Inlet Manifold—Front right and rear left

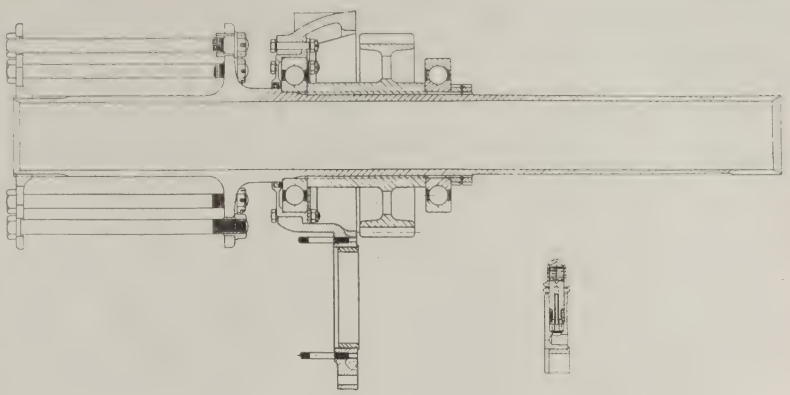
Crankshafts for the King-Bugatti Aviation Motor

Crankshaft

The crankshaft is made in two pieces connected at the center by a taper and key drawn up with a nut. Each section of the shaft forms a four cylinder shaft with the throws all in one plane, the throws of the two sections being assembled at right angles. In assembling, the rear end of the front half is immersed in boiling water, the tapering end of the rear section which is cold is then slipped into position and the parts drawn together by the nut using a long handled wrench.

The rear end of each complete shaft has clutch teeth cut on it for attaching a starter.

All end thrust coming on the shaft is taken by the center or No. 5 bearing all the other bearings having about 1/16" clearance at both ends.



All bearings, including the connecting rod bearings, with the exception of the center main bearing are undercut. This results in a total shortening of the shaft of approximately 4 31/32". This of course results in a considerable saving in the weight of various parts while still allowing ample bearing surface.

The crankshaft main bearings are bronze bushing, babbitt lined. These bearings are not relieved at the parting line and there are no oil grooves excepting in the lower half of bearings No. 1, No. 2, No. 3, No. 4, No. 6, No. 7, No. 8. These have a 3/32" wide x 1/32" deep circular oil groove entirely around them. This groove registers with the oil into the hollow crankshaft

bearing. As this oil hole is drilled through both walls of the bearing on a diameter and as the oil groove in the bushing extends through 180° there is always a free passage for the oil from the bearing into the hollow crankshaft.

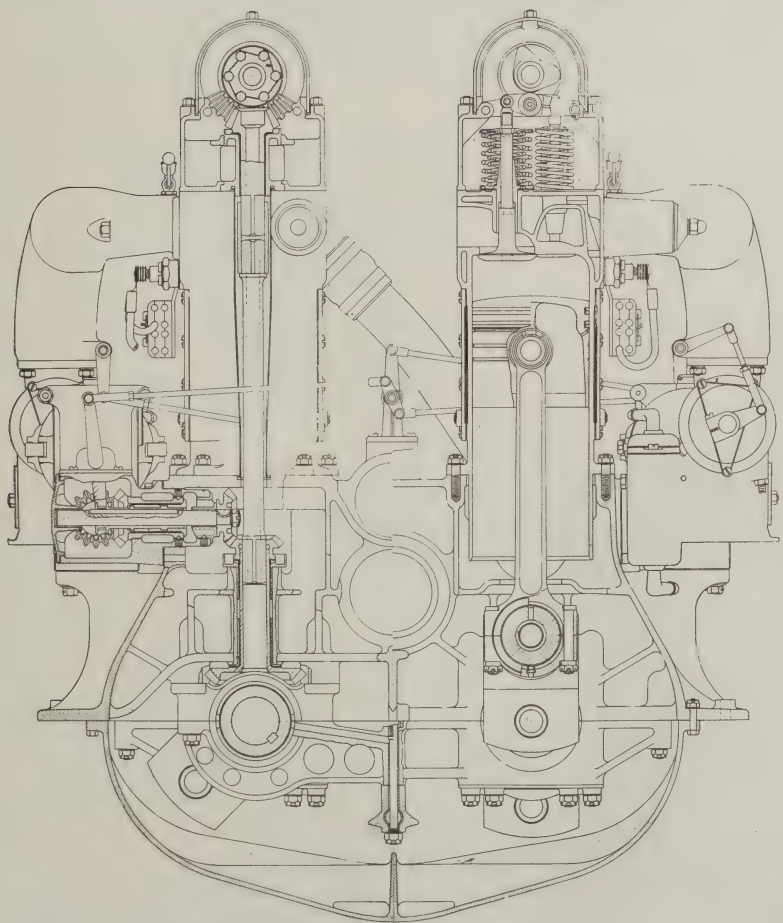
In assembling the completed crankshafts in the crankcase, they are placed in such a relation to each other that if No. 8 throw left is on top dead center No. 8 throw right will be 45° past bottom dead center. Both cranks turn clockwise viewed from the rear of the engine.

The propeller driving gears are bolted to the crankshaft with nine bolts equally spaced, the bolt holes being drilled in a certain relation to the gear teeth. This makes it possible to use the same gear on either shaft with a maximum error in the setting of the shafts of 20 minutes. The flange on the crankshaft and the gears are marked as indicated in Fig. 51 for the proper position of assembly of the gears on the shafts.

Propeller shaft and front cover assembly

Cylinders

The cylinders are of iron cast in blocks of four. They are bolted directly to the top of the crankcase without the use of a gasket. The water jacket is cast integral with the exception of the sides of the cylinder block below the inlet and exhaust ports, which are covered with a cast aluminum plate attached with screws. A gasket is used between these plates and the cylinder.



Cylinders are cast with separate exhaust ports. One inlet port supplies two cylinders. Two outlet and one exhaust valves are used.

The entire combustion space is machined with the exception of a very small recess near the inlet valve seat.

The tops of the cylinder blocks are machined, making an oil tight joint with the camshaft housing without the use of a gasket.

Provision is made for a liberal circulation of water in the neighborhood of the valve ports, seats and guides overcoming valve trouble.

Spark plugs, of which there are two per cylinder, are located at the side of the combustion chamber in close proximity to the inlet valves and are well cooled by the circulating water.

Bugatti 16 cylinder 410 H.P. engine—Sectional view

Crankcase

The crankcase and oil pan are of cast aluminum. The case is well ribbed. All bearings are supported from the upper part of the case, the bearing bushings being held in place by caps which extend almost the full width of the case. Each cap supports two bearings. They are all of cast aluminum with the exception of the center bearing cap, which takes all the thrust of the crankshaft. This is a steel forging.

The oil pan has a web running its entire length along the center line of the engine. This greatly assists in preventing the current of air caused by the revolving crankshafts from drawing up the oil which is constantly draining into the pan. There is also a cross web between each cylinder block which runs well up the sides of the oil pan. There cross webs have an opening at the bottom at their center, allowing the oil to drain to the ends of the pan on either side of the web running lengthwise.

A breather is attached to the top of the crankcase near the front end between the cylinder blocks.

Provision is made at the rear end of the case for attaching a 37 m.m. cannon, the barrel of the cannon projecting through the hollow propeller shaft.

Gun Control

Provision is made for attaching two gun control mechanisms, one at the rear end of each of the camshaft housings driven directly from the camshafts through a slotted coupling. When this control mechanism is used it is inserted in place of the camshaft housing end bearing cover.

Tachometer Drive

The tachometer drive may be taken from either end of the two camshafts. It operates at camshaft speed through a slotted coupling as indicated in the illustration.

When the gun control mechanism is used the tachometer drive is taken from the rear end through the same type of coupling as when driven directly from the end of the camshaft.

Cited for Bravery

First Lieut. Hermon C. Rorison, Aviation Section, 22d Aero Squadron. For extraordinary heroism in action near Beaumont, France, November 3, 1918. While on a bombing mission with five other pilots, Lieut. Rorison's patrol was attacked by 18 enemy planes (Fokker type). Three of his comrades were immediately shot down, but he continued in the fight for 30 minutes and destroyed two Fokkers, which were attacking the other two members of his patrol. With his plane badly damaged and himself wounded, he succeeded in shooting down another Fokker just before one of his guns was put out of action. By skillfully maneuvering he shook off the rest of the Fokkers and reached his lines, 15 miles away, in safety. Home address, Charles C. Chadbourn, uncle, Wilmington, N. C.

Air Heroes Returning from Abroad

January 22nd—Lieutenant W. P. Erwin of Chicago, winner of the Distinguished Service Cross, the French War Cross and the Aero Club of America Gold Medal, who has been officially credited with downing nine enemy planes, returned from France aboard the S. S. George Washington.

Major M. A. Hall, Wing Commander of the First Army who served with the British forces prior to America's entry in the war was also on the S. S. George Washington. He has been honored by a Croix de Guerre with a palm, the Distinguished Service Cross, twice given the Belgian War Cross and also the Order of Chevalier of the Order of the Crown. Major Hall took part in fighting at Chateau-Thierry, the Marne, the Vesle, St. Mihiel, the Argonne and at Verdun.

Ensigns Ludlow and Hamman, members of the American Naval Air Service, returned aboard the S. S. Giuseppi Verdi. These aviators distinguished themselves in air fighting on the Austrian front.

Secretary Daniels Commends Lieut. Gates for Rescue of Two Britons

Lieut. A. L. Gates, former Yale football player, who was taken prisoner by the Germans after having been forced to descend while on an air raid with a French squadron last October, has been commended by Secretary Daniels for his gallant conduct in rescuing two aviators from a British machine which had been wrecked off Ostend on August 22, 1918.

When word came to the American naval air station that the British fliers were down, Lieut. Gates immediately set out in his seaplane to rescue them. That he might have greater passenger-carrying capacity, he went up without gun layers, although he thus made it impossible to defend himself against enemy attack.

Vice Admiral Sims, commanding the American naval forces in Europe, recommended that Lieut. Gates be given a medal of honor. He inclosed with his report letters received from the British air ministry giving the details of the exploit and stating that the American lieutenant on several occasions had rendered very valuable assistance to British machines.

Lieut. Gates' home is in Clinton, Iowa. He was released from Germany after the armistice was signed.

Reserve Officers Training Courses to Continue

A recent report of the Committee on Education and Special Training shows that the educational institutions of this country are ready and eager to co-operate with the War Department in the training of reserve officers for the Army. Requests for the privilege of establishing units of the Reserve Officers' Training Corps have been received from more than three hundred and fifty institutions, including practically all the larger universities and colleges as well as many of the smaller schools and high schools. About two hundred and fifty of these schools have been authorized to maintain these schools, and officers are being assigned as Professors of Military Science and Tactics.

Attention will be given to keeping every young man physically fit by the establishment of a physical training system that will give every young man an opportunity for development. Summer camps to last for a period of six weeks will be maintained at Government expense.

Wood Urges Preparedness for the Next War

Topeka, Kansas, January 23rd.—In arguing for Universal Military Training, Major-General Leonard Wood made a strong appeal for preparedness for defense in the next war. His plan is to train youths for not more than six months, with a view to maintaining the smallest necessary standing army yet creating a huge reserve for national and international emergencies.

Dr. Thomas Eldridge Speaks On Aeronautics In Peace and War

Philadelphia, Pa., January 30th.—Dr. Thomas Edwin Eldridge, President of the Philadelphia Aeronautic Recreation Society, and prominent member of the United States Aeronautic Reserve, spoke before the Franklin Institute on Ballooning and Aviation in Peace, War, and Commerce, on January 30th.

The lecturer presented a brief history of Ballooning and Aviation, after which he described various types of aircraft from the earliest glider to the heavy armored battleplane, and took up development of aerostatics from the days of the early free balloon to the high-powered dirigibles of today.

Dr. Elderdige's talk was illustrated by excellent slides and punctuated by interesting reminiscences of his own experience.

Book Review

Model Making, Including Workshop, Practice, Design & Construction of Models. For Amateur and Professional Mechanics, by Raymond F. Yates.

This book does NOT describe the construction of toys. Its pages are devoted to model engineering and the mechanical sciences associated with it. It contains descriptions with illustrations of the complete models made by some of the leading model engineers in this country. It is the only book published on this important subject.

The first part of the book is devoted to the mechanical sciences and processes related to model engineering and mechanics in general. To the inexperienced workman, who wishes to make models but is untrained in the fundamental mechanics, this book will afford all the information necessary. For the experienced mechanics, there are many hints and shortcuts that will be found helpful.

Few model builders are familiar with pattern making; a portion of the book is therefore devoted to explanation of fundamental principles. There is a practical discussion on the utilization of abrasives in the home shop. In a like manner, all phases of construction for the model builder are thoroughly covered, and no model builder will fail to gain some labor-saving ideas from a perusal of the volume. The book is full of suggestions for those who like to make things, amateur and professional alike. It has been prepared especially for men with mechanical hobbies. Some may be engineers, machinists, jewellers, patterns makers, office clerks or bank presidents. It tells them "how-to-do" and "how-to-make" things in simple, understandable terms. It is full of good, clear working drawings and photographs of the models and apparatus described. Each model has been constructed and actually works if it is made according to directions.

Chapters: I, The Model Engineers' Workshop; II, Lathes and Lathe Work; III, Drills and Drilling; IV, Soft and Hard Soldering; V, Hardening and Tempering Steel; VI, The Use of Abrasives; VII, Pattern Making; VIII, Electroplating; IX, A Model Slide Crank Steam Engine; X, A Model Slide Crank Steam Engine; XI, A Single Cylinder Engine; XII, A Model Twin-cylinder Marine Engine; XIII, Flash Steam Plants; XIV, A Flash Steam Plant for Large Model Aeroplanes; XV, A Flash Steam Plant for Small Model Aeroplanes; XVI, A Model Steam Turbine; XVII, Design and Construction of Model Boilers; XVIII, Model Boiler Fittings; XIX, A Record Breaking Model Hydroaeroplane; XX, A Model Lake Freighter; XXI, A Sharpie-Type Model Boat; XXII, A Model Submarine Chaser; XXIII, A Model Submarine with Radio Control; XXIV, A Model Crane; XXV, An Electric Double Drum Hoist; XXVI, A Model Gasoline Engine; XXVII, A Model Electric Locomotive; XXVIII, A Model Steam Locomotive; XXIX, A Model Gyroscope Railroad; XXX, A Model Caterpillar Tank; XXXI, A Model Siege Gun.

This book can be purchased at The Aeronautic Library, Inc., 299 Madison Ave., N. Y. C., at the price of $3.25 postpaid.

Gen. Kenly Talks to Aviator in Plane from Washington Office

Communication between an aeroplane in the air and a regular telephone on the Washington city line was established recently at the office of Major General William L. Kenly, Director of Military Aeronautics. Although regular radio telephonic conversation frequently has been held with planes in the air at flying fields, this is the first demonstration of the combination of the radio-phone and regular land telephone.

General Kenly, Colonel F. R. Kenney and Colonel C. C. Culver were present in the office of the Director of Military Aeronautics and talked with Lieutenant Lucas, who was piloting a plane from Bolling Field. The two links in the line were the radio-telephone from the plane to the small station at Bolling Field, and the city telephone system from Bolling Field to General Kenly's office. The conversation of radio to direct wire was made automatically at the Bolling Field station with apparatus devised by members of the Air Service Radio Branch under the direction of Colonel Culver.

With the audibility of the modern trans-continental system, Colonel Culver believes that there is no limit to the distance over which a man in a plane in the air can speak with land telephones.

An Italian Observation Balloon with two smaller balloons for carrying cables

FOREIGN NEWS

Chili Establishes Air Service

Valparaiso.—The first consignment of aircraft, a purchase from the British Government, has reached Valparaiso. The entire contract calls for 14 seaplanes and 50 aeroplanes. Major Huston of the Royal Air Force will be instructor for the new force, and Lieutenant Solano will be in charge of Technical Engineering.

Farman "Goliath" Bomber Refitted for Commerce

Paris.—The Farman "Goliath" bomber ready for trial the day the armistice was signed, equipped with two Salmson Motors giving 540 H.P. and a speed of 90 M.P.H., has been refitted for commercial use. Heating apparatus is provided, and there is accommodation for thirty passengers. It is probable that it will be used in London-Paris service.

German Air Routes in Operation

London.—A dispatch from Copenhagen states that aerial mail and passenger routes are in daily operation between all the large cities of Germany. A fare of 2½ marks per mile is charged. The machines fly at a speed of 80 miles an hour, and the journey from Berlin to Munich, Cologne or Konigsberg takes 4½ hours. The Schutte-Lanz Company is constructing a new type of aeroplane to carry 40 passengers.

Air Service for Prince Edward Island

At a meeting of business men at Charlottetown, it was resolved to organize an aerial transport service between Prince Edward Island and the mainland for handling mail and express matter.

The initial route is to be via Moncton, Summerside, Charlottetown, Georgetown, Pictou, New Glasgow and Halifax.

Zeppelin Contemplating Transatlantic Service

From information transmitted from Switzerland through Paris, it is learned that the Zeppelin Company is considering the establishment of a dirigible service from Hamburg to New York. The ships are to provide for 80 passengers and luggage and fly at 56 M.P.H., thus accomplishing the journey in 85 hours.

Major-General Sykes, Chief of Air Staff, Gives Out Air Service Figures

London—In an address before the London Chamber of Commerce, General F. H. Sykes alluded to the greatly increased safety of flying, and to support his statement said that despite the strenuous conditions of military flying and training, only one fatal accident occurred in every 1,170 hours of flying. The total flying done since January, 1916, amounts to more than 1,000,000 hours or 114 years. A short distance high speed passenger service was inaugurated during the war for the transportation of staff and diplomatic officers, consisting of two flights of De Haviland 4's. During the four months of July, August, September and October of this year 227 trips were made, 8,085 miles crossed and 1,843 passengers transported. Of the 123 days of the period, cross channel flying was possible 71 days or approximately 60 per cent. One pilot in this service had made no less than 287 cross channel flights.

A Voisin pusher, used for photography and bombing in 1916

German Order Reveals Effectiveness of Voice Conrtolled Aircraft

Following the announcement of the Director of Military Aeronautics that the War Department had developed successful radio telephones for aircraft, permitting the direction of combat squadrons by the commander of the flight as perfectly and quickly as a squad of men, it was learned that so great an advantage had this proven in combats with German squadrons that an order was issued to shoot down a plane equipped with radiophones at any cost.

Holt Thomas Organization Strengthening

Mr. Holt Thomas is gathering into his organizations the best brains of the aeronautic world. Mr. Thomas has controlling interest in Aircraft Travel and Transport, Ltd., Aircraft Manufacturing Company, Ltd., Airship, Ltd., and the British Gnome and Le Rhone Engine Company.

Major-General Sir W. S. Brancker has recently become identified with the Thomas interests. Mr. Thomas' department heads include Lieutenant-Colonel M. O'Gorman, technical consultant; Captain Goefrey de Haviland, chief designer, who designed the DH4 and DH9 machines; Mr. Alfred Turner, financial director, late Director of Aeronautical Contracts, War Office; and Mr. Hugh Burroughes, general manager, late of the Royal Aircraft Factory.

Winston Churchill Made British Air Secretary

London, England.—Winston Churchill has been appointed to both the portfolio of Secretary of State for War and for Air.

Major-General J. E. B. Seely has been appointed Under-Secretary for the Air and presides over the Air Ministry.

Germans Slow in Surrendering Aircraft

The Germans have been delaying the turning over the requisite number of aircraft and motors in accordance with the armistice terms. They are 600 aeroplanes and 4,736 engines short of what should have been delivered within a month of the signing of the armistice.

Prince of Wales Flies Over Rhine in American Plane

During his visit at Coblenz, while visiting an American aerodrome there, the Prince of Wales flew over the Rhine with Colonel Mitchell, in command of the camp.

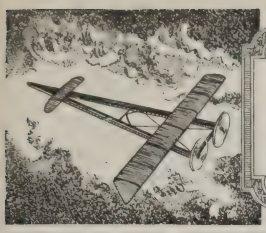
Chaplain-in-Chief, Royal Air Force

Rev. H. D. L. Viener, formerly chaplain in the Royal Navy, organized the Chaplain's Department in the Royal Air Force. He has been gazetted Chaplain-in-Chief for the R.A.F.

War Production in England

As an example of the tremendous output of the British industry for war purposes, a British trade publication announces that Messrs. Armstrong, Whitworth & Company, in addition to constructing 1,075 aeroplanes and three airships, used their spare time in turning out 13,000 guns, 12,000 gun mountings, 14,500,000 shells, 18,000,000 fuses, 21,000,000 cartridge cases, 47 warships, 22 merchant ships and fitted with armament 583 war vessels.

Allied Air Victories Summarized



According to figures recently compiled, 227 Allied Aces obtained 2,895 victories, while the Central Powers had 101 aces with an aggregate score of 1,629 victories; France being second with 77 Aces and 847 victories; Italy third with 14 Aces and 193 victories; United States, 14 and 121; Belgium, 8 and 77; Russia, 3 and 28.

Mexican Air Service Aids in Suppression of Revolts

Mexico City. — General Candido Aguilar, Chief of Military Operations in the Gulf Regions, is using aeroplanes in his operations against the rebels in the Vera Cruz district. Not only have the aviators done valuable reconnaissance work, but have engaged in bombing expeditions against parties of bandits who have considered themselves safely hidden in recesses of the Orizaba Mountains.

Restrictions On Hydrogen Removed

London.—The Hydrogen Order of 1918, which stipulated that the manufacture, sale and supply of compressed hydrogen in the United Kingdom should be controlled by the Deputy-Controller for Armament Production of the Admiralty and requiring returns to be made, had been cancelled.

Model Aeroplane Building as a Step to Aeronautical Engineering

THE next step would be to assemble the machine for its tryout. Before doing this each part must be examined and tested. Brace wires looked after, controls must be free and easy working, engine must be fastened securely to its bed and every wire and turnbuckle in the body must be tight and rigid because many forces act on a machine in the air and it is well to remember that an aeroplane like everything else is only as strong as its weakest point.

After looking these important things over we can assemble the machine.

The engine is set in place in the body as the first step and connected up to the ignition and gas controls, etc., the radiator is then bolted on. The landing chassis is next put in place and fastened, after which the propeller is bolted to the propeller hub. The engine covering can then be fastened with small screws, and the false work or turtle deck put in place.

The tail works and rudder must now be carefully set up and fastened to the body. Be sure that they line up properly. This can be judged fairly accurate by standing in front and facing the machine to see that the tail is horizontally correct and fastened securely to the control arms.

The wings are now attached. The center section first and then the outer sections.

When attaching the wings, fasten the lower sections in place first and place some kind of a support at the outer end so the plane will be on a line with the lower part of the body where it butts into, then fasten the top plane in place and put two outer struts in between them, after which the other struts can be inserted, and the same for the other side.

When this operation is finished the wings should be trued up. You will remember that the wings have a dihedral of 3 degrees, which means that the outer end of the wing must be about 2½" higher than the inside, where it fastens to the body.

When all brace wires are drawn up tight and you are sure nothing has been forgotten connect up the ailerons and see that they work properly.

The machine is assembled and we can see if our theoretical balance was correct by placing a couple of wooden horses or other supports on each side of the body and placing a beam on these supports at a point on the body where we thought our balance should be. Of course a person must be sitting in the pilot's seat or the machine won't balance properly.

If when this test is made the machine shows to be heavier on the nose you need not worry as a little nose heaviness will not matter much, but if on the other hand it is heavier on the tail, then it means a hard job to control the machine as it will be sluggish when trying to get the tail up.

Perhaps a few words can be said in regard to flying the "bus." I need not suggest that an experienced pilot should try it out first because everyone knows that a new machine is cranky and unless the pilot has had a good deal of flying experience trouble might be encountered.

If it is impossible to get an experienced pilot to test the machine, the builder should practice very carefully by taxying the machine over the ground very slowly with engine throttled low, so that there will be no danger of the machine lifting clear of the ground. In this way the very peculiar foot bar rudder control can be mastered. When this has been done a half dozen times the engine should be speeded up a little more and short hops a trifle off the ground should be made by pulling the control stick back gently a short distance and then letting it go back to normal again. In a very short time you will find that you are getting confident and that you can do lots of things, and before you realize you will be making long hops and a little later low flights. Don't rush this part of the flying course, as it is best to go slow, getting wise to every feel of the machine when the control stick or rudder bar is moved. A person learning to fly is much like an infant learning to walk, and the same patience that it takes to assist and teach a child to walk must be exercised with the budding air pilot. Remember that practice makes perfect and many times a smash up helps us to generate more nerve than if nothing like that occurred.

Perspective sketch of the Ford Motored Aeroplane of which the series of articles describing its construction is concluded in this issue

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Byng!

Byng! Byng! Byng!!!
With your smashin'
Of the 'Un upon the wing—
And your chargin' and your shootin'
And your dashin' and your scootin',
And your yellin' and your hootin'—
That's the thing.

When you start to advancin',
With a punch in left and right,
We all feel safe in chancin'
All we've got upon your fight.

Biff! Bang!! Byng!!!
Your orders always have
The proper ring.
And we tell you, on the level,
All the 'Uns think you're a devil,
When you get into a shindy,
You're a greater man than Hindy,
Mister Byng.

Manoeuvers at Mineola

Up the wind, coasting, you come,
Straight, with the sweep of a gull;
On, on, with your heart athrob,
And wide wings, grayly dull.

Turning, a dragon-fly skims,
Flashing her silvery tail;
Circling. . . .then with a dip,
Lost where the soft clouds trail.

MARGARET L. SEAMAN.

From Ellington Field Tale Spins

"The Reason Why"

One hundred German aeroplanes flying in the sky,
Along comes a Yank ace, and now they're one shy.
Nine and ninety battle planes still hovering on high,
But a bullet from an "Anti" keeps one from getting by.
The ninety-eight were scudding along above the rye,
When one fell a victim to a rookie's lucky try.
Now seven and ninety Taubes are getting mighty "nigh,"
But an Allied squadron hits them and twenty-seven die.
Seventy Huns are winging to the rear on the fly,
Pursued by the victors with their lusty battle cry.
Popping machine guns pick off the slower fry,
Until upon the ground full forty of them lie.
The thirty planes remaining think they're pretty sly,
Until a squadron bombed them and that spelled good-bye.
If for this mighty victory you seek a reason why,
Just ask in Portland, Oregon, for that spruce-producing guy.

—*The Peavey.*

Air Knights

The horrors of war as seen from the air
Are few, 'tis well worth the thrill
For the battles are clean, and the fighting is fair,
Death is dealt or prevented by skill.

The hum of the motor, sing of the wires,
Furnish music of highest art,
And the rattling beat as the machine gun fires
Is dear to the bird man's heart.

Like knights of old enclothed in steel,
But mounted on winged steeds
They fight, and dive or soar and reek
To accomplish valorous deeds.

When the days of peace come to the earth,
And the knights of the air return,
The country will see their truest worth,
In making the fires of industry burn.

G. M. Hickok.

Oh You Aviation Vocabulary!

Mechanic (reading magazine): What does this here "Danse du derriere" mean?

Crew Chief: Why, you simp, that's French for "tail-spin"!

He Wants a Penguin

One of the older ground officers remarked the other day: "There's no earthly use in my learning to fly a plane!"—*Rockville Field News.*

Those who are closing their military careers as lieutenants may take heart from this remark of a distinguished clergyman to the writer of these lines in response to his statement that he was "only a lieutenant." The minister said: "Lieutenant, why that is the most honorable rank in the army. You and I have heard every boat pilot and wharf lounger called 'captain' and every village store loafer 'major' or 'colonel,' and sometimes even 'general,' but we never heard anyone but a real soldier called 'lieutenant.'"

Little Mary Calls Him Up at Taliaferro Field

Operator: Taliaferro Field.

Little Mary: I want to speak to Sergeant S———; he's a hangar man, he hangs around the hangar."

from which would follow:

$$Wx = \frac{M'x}{2\ \delta o\ [ho + \alpha x]} + \frac{M''x}{2\ \delta o\ [\lambda o + \beta x]}$$

If we fix δo from the quality of the wood employed, and the factor of safety sought, the values α, β, λo, ho will also be determined so that the required section of the material will be obtained.

In order to find this section it is necessary to determine to what extent the plywood covering helps to resist the stresses.

Tests which have been made have shown that the section Wx may be considered as made up of the longeron m, n, r, s and of a portion A, B, C — A, D, E of the covering working in conjunction with the longeron itself and utilizing DE and BC may be considered equal to $20.S$, where S is the thickness of the plywood. (Fig. 3.)

$\therefore$ Wx may be obtained from the formula

$$Wx = [h \times l] + 2 \times 20.\overline{S}^{2}$$

In calculating the shearing stresses it is best to plot them. This evidently will depend on the distribution of the strains along the fuselage. Having once determined from such diagrams the value of the reaction T, and the sectional area on which this acts; it may be considered that one-half of this reaction will be taken care of by the plywood acting in tension and the other half by the diagonal bracing at the sides which stiffens the structure.

Therefore the stress on the plywood will be

$$\delta = \frac{\frac{T}{2}}{h\ [2 \times S]}$$

For the stress in the diagonals, it will be easy to find the value along the diagonal in compression which we will call T_1 (this value being for both diagonals).

The minimum moment of inertia will be (Fig. 4)

$$Ixo = Ix - \frac{\overline{S}^{2}}{A}$$

where S is static moment of the section with respect to XX, and A the area of section of the diagonal as well as that of the plywood acting with it.

The diagonals may be considered as being completely fixed at both ends. Therefore it will be easy to determine the stress at the proposed section.

The more detailed and exact is the analysis of the stresses made, the more advantageously will the material be utilized resulting in a great saving of weight.

The plywood fuselage which has already found complete use in the small and medium sized machines has encountered some difficulty in the large machines and this because of the large resulting weight. However, it may be foreseen that in the very near future, these difficulties will be eliminated.

Recently tests have been conducted on fuselages made of wood, in which the longitudinal longerons running the full length of the fuselage have been eliminated as well as the stiffening ribs.

Such a fuselage would be made by moulding on mould representing the fuselage very thin sheets of wood with fibre running perpendicular to one another, and then removing the shell from the mould when completed.

These tests have already given good results and it seems as though they will lead to a practical result which would bring a great advantage in weight.

provide better contacts, and to prevent corrosion. Other contact parts are of hard brass silver or nickel plated. All of the springs employed are of phosphor-bronz. The electrical connections between the instrument base, and its cover are by means of substantial screws which act not only as binding posts, but as attachment members holding the cover in place. These are all protected by castelled nuts and cotter pins. Dielectric parts consist of bakelite castings. Owing to the extended development and tests involved, the instrument did not get into quantity production until December 1918.

It is claimed for the interrupter that it offers an insurance against those supplemental injuries to the machine which are sure to follow from propeller breaking in flight. These injuries range from concealed strains to a fatal crash. Forgetting for the moment the loss of life, however important, and viewing the subject from the point of the monetary loss only, with planes costing from $5,000 to $50,000 apiece with equipment, the comparative cost of this insurance is trifling.

While by no means the most frequent cause of fatal accidents, the danger of fire in the air, or after a crash, is without doubt the most feared by pilots and passengers alike, as it is the most difficult danger to guard against, and any instrument tending to lessen this hazard is of decided value and will accomplish much toward increasing confidence in the safety of aerial navigation, which must mean better morale among pilots, observers, gunners, etc., and for the ordinary passenger a greater feeling of safety and security.

The success of the commercial aeroplane will depend in a large measure upon engineering skill to minimize danger and upon the ability of aerial passenger companies to convince the public that a trip in the air is free from any extraordinary risk.

Cited for Bravery

First Lieut. Russell L. Maughan, Aviation Section, 139th Aero Squadron. For extraordinary heroism in action near Sommerance, France, October 27, 1918. Accompanied by two other planes, Lieut. Maughan was patrolling our lines when he saw slightly below him an enemy plane (Fokker type). When he started an attack upon it he was attacked from behind by four more of the enemy. By several well-directed shots he sent one of his opponents to the earth, and, although the forces of the enemy were again increased by seven planes, he so skillfully maneuvered that he was able to escape toward his lines. While returning he attacked and brought down an enemy plane which was diving on our trenches. Home address, Peter W. Maughan, father, Logan, Utah.

First Lieut. William J. Hoover, Aviation Section, 27th Aero Squadron. For extraordinary heroism in action near Verdilly, France, July 2, 1918. On the morning of July 2 his flight patrol encountered the famous Richthofen circus. Lieut. Hoover was simultaneously attacked by three of the enemy and cut off from his comrades. By skillfully maneuvering he avoided the effects of their concentrated fire and fearlessly attacked the three. Although his machine was seriously damaged, he killed one of the enemy pilots and destroyed his plane, drove down another, apparently out of control, and chased the third far into his own lines. He then continued his patrol until shortage of gasoline forced him to return. Home address, Mrs. William J. Hoover, Hartsville, S. C.

EVERY FIRST CLASS AEROPLANE REQUIRES A RETRACTABLE CHASSIS

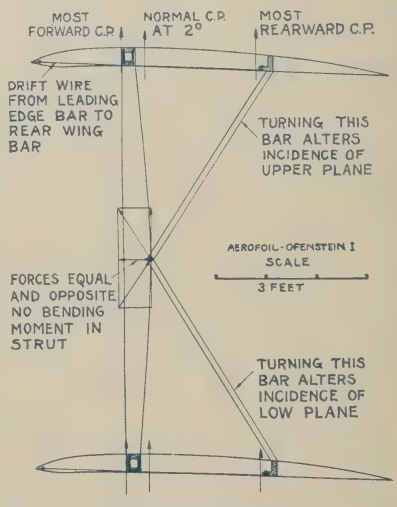
COMPARISON OF RESISTANCE AND WEIGHT OF K-BAR AND DOUBLE LIFT TRUSS SYSTEMS

The following is an exact Comparison of Resistance and Weight:

At a speed of 100 M.P.H.,
Wing loading of 9#/sq. ft.,
Safety factor of 8,
Aspect ratio of 6,
Gap/chord ratio of K-Bar Truss...1.143
Gap/chord ratio of Double Lift Truss...1.000

Resistance of K-Bar Truss is $\frac{97.2}{185.0}$ = 52.5% of resistance of Double Lift Truss.

Weight of K-Bar Truss is $\frac{106.45}{146.57}$ = 72.7% weight of Double Lift Truss.



The K-bar Truss reduces interference by eliminating interplane struts and wires and also by affording increased Gap cord ratio. Normal C. R. always near central wing bar, only light forces at most rearward C. P.

"NORMA"
PRECISION
BALL BEARINGS
(PATENTED)

A machine, a mechanism, reflects the character of its builder. From the performance of that machine or mechanism, the user forms his estimate of the standards, the integrity, of the manufacturer. Inadequately in some seemingly minor part evidences carelessness and neglect and calls in question not only the worth of the machine but also the character of the man who made it.

Manufacturers of ignition apparatus and lighting generators using "NORMA" Ball Bearings, fear no bearing troubles or failures. And builders of airplanes, cars, trucks, tractors and power boats carrying this high-grade apparatus, fear no criticism due to trouble with their electrical equipment.

Be SURE. See that your Electrical Apparatus is "NORMA" Equipped.

A Great Naval Achievement

The remarkable flying boat shown in the photograph above is one of the epoch making achievements of naval aviation. It is the largest flying boat in the world—a craft capable of flying with eleven (11) tons. This same naval plane recently flew with fifty Navy men and pilot aboard.

Developed and built at The Curtiss Engineering Corporation, Garden City, by Naval Constructors working in collaboration with Glenn H. Curtiss and his engineers, it stands today as a proved product of unquestioned superiority, entirely American in its conception, evolution, manufacture and performance.

AERO CLUB OF AMERICA BANQUET STARTS MOVEMENT TO DEVELOP AMERICAN AERONAUTICS ON PERMANENT BASIS

A SUBSTANTIAL movement to start the development of American civilian aeronautics on an extensive scale, and prevent the United States from again falling behind other nations aeronautically was launched at the Thirteenth Annual Banquet of the Aero Club of America held last night at the Waldorf-Astoria, Wednesday, February 19.

One thousand people attended the banquet, including many prominent Army, Navy, Marine Corps and Allied aeronautic authorities and aces.

Sitting on the diaz were: Major-General Charles T. Menoher, Director of the United States Army Air Service; Colonel James A. Mars, Director of Aircraft Production, U. S. Army; Captain Lahauille, the French Ace, and one of the highest French authorities in military aeronautics, who was sent especially by the French Government to represent French aeronautics at the banquet; Rear-Admiral Bradley A. Fiske, U. S. Navy; Major General William L. Kenly, Director of Military Aeronautics, U. S. Army; Brigadier-General J. D. Cormac, Chief of the British Aviation Mission to the United States; Colonel A. L. Fuller, Chief of Balloon Section, U. S. Army; Colonel Milton F. Davis, Division of Military Aeronautics; Captain Carlo Tappi, Italian Ace, veteran of the Turkish-Italian War of 1911, and also the Great War, who was one of the first six aviators in the world to be employed in aerial warfare; Mr. Henry Fairfield Osborn, President of the American Museum of Natural History; Mr. F. H. Russell, President of the Manufacturers' Aircraft Association; Captain Robert A. Bartlett, the famous arctic explorer, who accompanied Admiral Peary to the North Pole; Mr. John Greenough, President of the American Geographical Society; Lieut. Colonel E. Lester Jones, Director of the U. S. Coast and Geodetic Survey; Brigadier-General Theodore C. Lyster, the head of the Medical Air Service, which supervised the examination of over 80,000 candidates for the Air Service, and classified them according to their physical fitness for flying; Hon. Francis M. Hugo, Secretary of the State of New York; Mr. John Hays Hammond, Jr., authority on Polar aerial radio surveying; Mr. Otto Praeger, Second Assistant Postmaster General; Mr. Rodman Wanamaker, Commissioner of Aviation Section, New York City Police; Mr. Alan R. Hawley, President of the Aero Club of America; Mr. Henry A. Wise Wood, Vice-President of the Aero Club of America; Mr. Henry Woodhouse, member of Board of Governors, Aero Club of America; Mr. Marcel Knecht, French High Commissioner; General Emilio Guglielmotti, Military Attache of the Royal Italian Embassy; Major Fiorello H. La Guardia, Member of Congress; Lieutenant De Carlo of the Italian Military Mission for Aeronautics; General Guy Livingstone, of the British Aviation Mission.

The banquet was the occasion for starting a number of movements and for the making of a number of announcements of great importance to American aeronautics.

W. K. Vanderbilt Gives $10,000 to the Bartlett Expedition

Some of the most important announcements were as follows:

(1) Mr. Alan R. Hawley, President of the Aero Club of America, announced that Mr. William K. Vanderbilt has given $10,000, and Mr. Charles H. Sabin has given $5,000 to start the $250,000 fund for the Roosevelt Aerial Arctic Expedition, which is to be commanded by Robert A. Bartlett, the famous explorer.

Hammond's Revolutionary Aero Radio Surveying

(2) Mr. John Hays Hammond, Jr., the noted inventor and radio expert, announced the completion of a plan whereby the work of making maps of the arctic regions, which the Roosevelt Expedition is to explore from the air, will be greatly simplified by use of radio devices. Two of these devices, which are very simple, will operate from the base, and by radio contact with the aeroplanes which will be flying over the unexplored regions will trace the movements of the planes on paper, so that when the aviators return to the base with their own sketches, they will find the tracings showing every movement they made. In other words, if the aviators follow the direction of an ice floe, or circle over a spot, which may look like land, the radio devices at the base will trace on paper the course which they followed, so that the aviators on returning can check their own sketches and get exact tracings of contours, etc., of the region which they have been exploring. At the same time, the people at the base, by following the tracings of these devices will know exactly where the aeroplanes are exploring.

This new conception of Mr. Hammond was pronounced as being revolutionary and greatly simplifying the work of exploration from the air, by the explorers present, including Captain Robert A. Bartlett; Mr. John Greenough, the Presi-

dent of the American Geographic Society, and Mr. Henry Fairfield Osborn, the President of the American Museum of Natural History.

Peary's Arousing Message

(3) The following arousing message was received from Rear-Admiral Robert E. Peary, the famous discoverer of the North Pole, and leader of the aerial preparedness movement, who could not attend the banquet owing to his illness:

"The United States is looking to the Aero Club of America to start a movement to develop aerial transportation and the employment of aircraft for general purposes, so as to prevent the United States from again falling behind other nations in this progressive line of human endeavor, which means so much to the future of the United States.

"Through the energetic and patriotic efforts of the Aero Club of America in arranging for the training of aviators at private expense in 1915-1916, there were 300 trained aviators ready for the U. S. Army and Navy when the United States entered into the war. The Club is to be congratulated for having continued the progressive work with the same foresight, in starting the movement to develop aerial transportation and the employment of aircraft for scientific and general purposes. The plan to send Captain Bartlett to explore the arctic regions from the air is an epoch-making event in the history of science and revolutionizes exploration, and the Club is to be commended for its very valuable contribution to science.

"Permit me to urge that you bring the attention of the country to the fact that today aeronautics offers even greater possibilities than the railroad field did to the Vanderbilts, Harriman, Hill, and other great railroad builders. The world is ready for aerial transportation and the men whose foresight leads them to put their efforts in establishing air lines will find aeronautics to offer greater possibilities than were offered by any other line of human endeavors.

"(Signed) Peary."

National Balloon Races

(4) Announcement was made that the arrangements have been completed for holding the national balloon races at St. Louis this year. The arrangements have been completed by Major A. B. Lambert of St. Louis, member of the Board of Governors of the Aero Club of America.

The International Races

(5) Mr. Alan R. Hawley read a cablegram from the Royal Aero Club of Great Britain, announcing that two entries have been received for the Trans-Atlantic flight, in competition for the $50,000 prize offered by Lord Northcliff for the first trans-Atlantic flight made within seventy-two hours from start to finish. The cable also states that the Royal Aero Club hopes to be able to arrange for the International Marine Flying contest for the $5,000 trophy and $5,000 prize, offered by Mr. Jacques Schneider, the French sportsman. If this arrangement can be made the Aero Club of America will arrange to enter a number of contestants to compete for this trophy.

(6) International conditions permitting, there will be held also international aviation and balloon races, one in France and one in the United States.

Pershing's Cable

(7) A cablegram was read from General Pershing, reading as follows:

"On the occasion of the Thirteenth Annual Banquet of the Aero Club, am glad to send the greetings of the Expeditionary Forces in France to the aviators of America. Four years of war have developed flying to a point beyond belief. American airmen have grasped their opportunity, have mastered the art and mechanics of flying, and have advanced still further the tactics of aviation our Allies taught us. We all take pride in their spirit of devotion, their gallantry, and their deeds of heroism. The Aero Club has an opportunity to bring peace time aviation to a dream of usefulness to the world which will in part compensate for the expenditure of blood and treasure during the war. "(Signed) PERSHING."

(8) The following cablegram from Paris, signed by Ambassador Sharp, Mr. Robert A. Bliss, Mr. Sidney B. Veit, Mr. John Weare, Dr. A. L. Hipwell, Mr. William S. Hogan, Mr. Louis D. Beaumont and Major Edmund L. Gros, and Mr. R. B. Price, was read:

"Ambassador Sharp, Bliss, Veit, Weare, Hipwell, Hogan, Price and Major Gros send hearty greetings to Aero Club and contgratulate men in active service for excellent achievement during war. Express deep sympathy and admiration for those whose self-sacrifice made victory possible. Urge continued efforts to sustain interest in future possibilities of aeronautics by actively participating in congress and in perfecting apparatus for aerial traffic.

"The first Trans-Atlantic flights should be America's credit.

"Please announce sailing March eighth French Government Aeronautical Mission of fifteen officers, Captain Lavergene, Chief, including Aces, Madon, Romanet; Marinouites, bringing latest models aeroplanes for competitive flights. Extensive exhibition, paintings, sculpture, films. Mission will visit all large cities by squadron flights and expect your patronage with active co-operation in regulating itinerary and arrangements for art exhibitions and lectures."

(9) General Menoher spoke hopefully of the United States maintaining a substantial air force and General Kenly expressed his appreciation of the splendid work performed during the past by the officers and enlisted men of the Division of Military Aeronautics. General Kenly's message reads as follows:

"To the Officers and Enlisted Men of the Air Service: It seems fitting at this time to express my appreciation of the splendid work performed for the past year or more of war activities, by the officers and enlisted men of the Division of Military Aeronautics. Many of you are now returning to civil pursuits with the regret that you were not among the more fortunate ones who experienced actual service overseas. To you who have labored night and day, undertaking hazardous duties in all weather, that the training of our fighting air men might continue without interruption, I express my sincere thanks for your steadfast devotion to a duty which so suddenly became apparent would involve little hope of commensurate reward. The interminable grind of performing the same hazardous duties over and over again in order that others less experienced might be fitted for the work in hand, and then to have your former students sent to the front while you "carry on"" requires a quality of pluck and steadfast determination which the fortunate few who have never experienced such heartrending disappointment can never understand.

"To those who serve overseas and return to this country with the satisfactory feeling of difficult duty well done, I offer my sincere congratulations for your worthy accomplishments.

"For those who met an untimely end in our service, I am sure we all hope that they may receive the reward they so justly merit for the extreme sacrifice.

"(Signed) W. L. KENLY,
"Major-General, U. S. A.,
"Director of Military Aeronautics."

Mackay Trophy Awarded to Rickenbacker

(10) The Clarence H. Mackay Trophy, offered through the Aero Club of America for Annual Army Competition, was awarded to Captain E. V. Rickenbacker, the Ace of American Aces. The award was made by a board appointed by General Kenly, consisting of: Colonel Townsend F. Dodd, Lieut. Colonel Byron Q. Jones; Lieut. Colonel Herbert A. Dargue and Lieut. Sidny T. Thomas. Captain Rickenbacker

could not be present at the banquet to receive the award, being prevented by military duties.

The Club's Medal of Valor and Diploma

(11) Announcement was made of the award of the Aero Club of America's Medal of Valor, together with the artistic steel engraved diploma, to the following Allied Aces and officers of the Allied Air Services:

United States

Major Raoul Lufberry, Corporal L. Norman Barclay, Corporal Julian C. Biddle, Corporal A. C. Campbell, Jr.; Corporal O. M. Chadwick; Lieut. V. K. Chapman, Sergeant Edmund C. Genet, Sergeant Ronald Hoskier, Sergeant James R. McConnell, Sergeant Douglas McMonagle, Lieut. Norman Prince, Sub-Lieut. Kiffin Yates Rockwell, Corporal Stuart Walcott, Lt. Col. William Thaw, Ensign A. D. Sturtevant, Ensign C. S. Read, Lieut. Douglas Campbell, Lieut. Frank Luke, Capt. Edward V. Rickenbacker, Capt. Frederick Libby, Lieut. Paul Pavelka, Lieut. Wm. Erwin, Lieut. Paul F. Baer, Lieut. Donald Hudson, Lieut. L. Holden, Lieut. James Knowles, Jr., Lieut. John McArthur, Lieut. Ralph O'Niell, Lieut. K. L. Porter, Lieut. Summer Sewell, Lieut. Wilbur T. White, Lieut. Harvey Cooks, Lieut. Edward Curtis, Lieut. James R. Healy, Lieut. M. Francis Simmonds, Lieut. Joseph Jehaner, Capt. Jas. Norman Hall, Capt. Harold B. Buckley, Capt. Reed M. Chambers, Major James A. Meissner, Capt. Hamilton Coolidge, Capt. C. J. Vasconcelle, Major Harold E. Hartney, Sergeant Frank L. Bayliss, Lieut. David E. Putnam, Major David McKay Peters, Lieut. L. W. Taylor, Lieut. L. C. Rehronbach, Lieut. Warren Higgs, Lieut. T. A. Rooney, Lieut. L. C. Bowers, Lieut. J. H. McDevitt, Lieut. C. J. Ross.

France

Capt. George Guynemer, Sub-Lieut. Rene Dorme, Adjt. Maxime Lenoir, Lieut. Jean Chaput, Lieut. Charles Nungesser, Lieut. Roland G. Carros, Capt. Rene Fonck, Capt. Alfred Herteaux, Lieut. Georges Felix Madon, Capt. Albert Leon Deullin, Capt. Armand Pineard, Sub-Lieut. Guerin, Sub-Lieut. Maurice Boyau, Sub-Lieut. Omer Demouldre, Lieut. Forest, Lieut. Marchal, Lieut. Coiffard.

Great Britain

Capt. Albert Ball, Capt. P. F. Fullard, Major William A. Bishop, Capt. James B. McCudden, Major Edward Mannock.

Italy

Major Francesco Barracca, Lieut. Olivari, Col. Jules Piccio, Lieut. Fulvio Barrachini, Major Gabriele d'Annunzio.

Belgium

Lieut. Thieffry, Lieut. Willy Coppens.

(12) Brigadier General Theodore C. Lyster, the head of the Medical Air Service, which supervised the examination of over 80,000 candidates for the Air Service and classified them according to their physical fitness for flying, spoke of the importance of the Aero Club of America continuing this supervision over civilian aviators. The work of the Medical Service was praised highly by the officers of the Aero Club of America.

(13) Major-General Leonard Wood, wrote from Camp Funston, Kansas, as follows:

"I earnestly hope that the Aero Club of America will push forward the work on aeronautics and put it on a sound basis in this country. We must never again be caught unprepared in the air."

(14) Mr. Hawley read a letter from Major John Henly, recommending the award of the Aero Club of America's Medal of Merit to army officers for notable achievements, as follows:

"The Director of Military Aeronautics."

"Aero Club of America, 297 Madison Avenue, New York, N. Y."

"Aero Club of America Medals of Merit."

1. A board of officers consisting of: Col. Townsend F. Dodd, M.A., A. S. A.; Lieut. Col. Herbert Q. Dargue, M.A., A. S. A.; Lieut. Col. Byron Q. Jones, M.A., A. S. A.; 1st Lieut. Sidney T. Thomas, A. S. A., has recommended that the Aero Club of America Medals of Merit be awarded to the following named officers for notable achievements in aeronautics:

Major Norman Boots, A. S. A.—Non-stop flight with passenger from Mt. Clemens, Mich., to Yonkers, N. Y., November 7, 1918.

Lieuts. Clifford Nutt and Ray Grantz, A. S. A.—Houston to Denver, Col. First aeroplane into Colorado under its own power. October 1, 1918.

Lieut. J. E. Davis, A. S. A.—Ellington Field, Texas, to Mt. Clemens, Mich., and return. Flying time 62 hours. October, 1918.

Major Albert D. Smith.—Transcontinental Flight, San Diego to Washington.

Mr. Caleb Bragg.—Dayton to Bolling Field, D. C., 430 miles.

Captain F. M. Bartlett, A. S. A.—Scott Field, Ill., to Kelly Field, Tex., 1,700 miles.

Major H. L. Armstrong, British Army, and Lt. Cyrus F. Smythe, pilot.—Flew over burning munitions plant at Morgan, N. J., directing fight against flames. Oct. 4, 1918.

Lieuts. C. M. Cone, Wm. B. Bancker, Jr., and Z. P. Lee, A. S. A.—Ellington Field, Tex., to Washington, D. C., 30 hours' flying time. October, 1918.

Lieuts. Grafton Wiggins and Charles M. Potter, A. S. A.—Aerial mapping and geographic work.

Lieut. Cyril Smith, A. S. A.—Aerial mapping of Ft. Sill.

Capt. Michael McKinney, A. S. A.—Aerial mapping of Washington, D. C.

Colonel C. C. Culver—Radio Telephone Research.

Lieuts. Paul R. Blair and Wm. T. Gobrecht, A. S. A.—Altitude 19,200 ft. Nov. 19, 1918.

Lieuts. W. H. Helmrich and A. W. Graham.—Altitude 18,000 ft. Nov. 6, 1918.

(*Signed*) W. L. Kenly,
Major General, U. S. Army.

Further award of Medals of Merit to officers of the Navy, Marine Corps, and others, was postponed pending the completion of the list of achievements for which the awards are to be made.

It is understood that a large number of the Club's Medals of Merit are to be awarded in the near future, and that when the announcements are made there will also be made announcements of marvelous technical and scientific achievements for which the Club's Medals are awarded.

Medals of Merit were also awarded to the following:

Commander P. N. L. Bellinger, for his flight of 667.92 miles without landing, in nine hours and one minute, carrying five passengers and 542 pounds additional weight, at Norfolk, Va., December 31, 1918.

Katherine Stinson, to commemorate her flight from Chicago to Binghamton, on May 23, 1918, when she established new duration and distance records of 10 hours 10 minutes, and 601,763 miles.

Capt. R. W. Schroeder, for having broken both the world and American altitude record, pilot alone. Sept. 18, 1918, attaining a height of 28,900 feet.

Major Bernard L. Smith, M. C., for making the first long-distance flight with the first twin-motored dirigible, "D-17," from Akron, Ohio, to New York, on the 22nd of October, 1918.

Lieut. R. A. D. Preston, U. S. N., R. F., for making the first long-distance flight with the first twin-motored dirigible, "D-17," from Akron, Ohio, to New York, on the 22nd of October, 1918.

Leading artists contributed greatly to make the event an inspiring one. Mr. Leon Rothier, the famous and celebrated tenor of the Metropolitan Opera Company, sang "La Marseillaise" in a most inspiring manner, and the Fort Slocum Post Band, in conjunction with Orlando's Orchestra, played appropriate pieces during the evening. The singing was led by Mr. Frederick Hall, who also played the large organ and a choir, led by Mr. John M. Fulton, sang selections during the evening. One of the greatest of hits was made by the inspiring aviation song, "Knights of the Air," written by the well-known playwright and composer, Lieutenant Earl Carroll, the "Composer of the Air." The invocation, at the beginning of the banquet, was delivered by the Rev. Doctor Percy Stickney Grant, of the Church of the Ascension.

THE NEWS OF THE WEEK

Captured Enemy Aircraft to be Exhibited at Aero Show

New York, N. Y.—It was announced that the War Department will exhibit several German aeroplanes, trophies of the war, at the Aeronautical Exposition at Madison Square Garden and the 69th Regiment Armory. There will be a late type of Fokker D-7, the combat craft of the enemy. Another machine is reported to be the German Rumpler. This is a reconnaissance type of machine, propelled by a 260 horsepower motor.

The Handley-Page bomber, the Spad and the S. E. 5 will be the English models shown; France will be represented by a Nieuporte and Breguet and Italy by a Caproni and an S. V. A.

In addition to displaying the accomplishments of aeronautical and automotive engineers during the last two years, the War Department's exhibit will show how the Air Service trained its aviators for foreign service. From March 1 to March 15—the period of the exposition—principles of training, equipment and instruments used, motion pictures of actual work, and the various machines which figured in the educational course of the pilot will be demonstrated.

The famous "whirling chair" will form part of this phase of the Army exhibit. It is used to test the prospective aviators' sense of balance and by its examining officers are able to determine if the applicant would be able to determine his position relative to the centre of gravity while flying through clouds. The chair will be at the disposal of all visitors who may care to use it.

Beginning with the medical tests and ending with the combat planes used on the other side, the exhibits will cover almost every phase of the pilot's instruction and work. Models of the war zone used in elementary ground schools will be operated by officers of the army to demonstrate to visitors just how these devices entered into the necessary curriculum; clothing and instruments used by aviators after they began actual flying will be shown, and ordnance—machine guns and bombs—will be demonstrated on the ships which have carried them in the war game.

Training ships, pursuit planes, reconnaissance machine and the big bombers will be included in the government's exhibits, and there will be types of English, French, Italian and German planes to compare with the American-made products.

The Division of Military Aeronautics will exhibit a Cacquot balloon, designed by Major Armand Cacquot of the French air service, and the accepted standard observation balloon. The Cacquot is distinguished by stabilizing finds and rudder at the stern, which are so designed as to keep the craft nosed into the wind.

"The Langley," the first American built Handley Page aeroplane is to be exhibited at the show. This plane is now near Washington, D. C., and will be flown to Long Island and brought to the 69th Regiment Armory by means of motor trucks.

The Navy Department will also exhibit a device whereby night landings are made safe for night commercial air traffic. Since any extensive use of aircraft for commercial purposes will involve a good deal of night landing, this device his important application in this field.

It has always been a problem in night landing to determine the exact time at which the aviator should "flatten out" to make an easy landing.

The Naval night altitude indicator consists of four spot lights whose rays are projected downward from the fuselage at such an angle that when an altitude of fifty feet is reached the two right and two left beams meet, forming a single spot on the ground. As the plane drops to a still lower altitude the beams again diverge, thus indicating the approximate distance from the ground. With a little practice the aviator is enabled to make very accurate landings with the assistance of this device.

The Navy Department will include a complete display of oxygen breather devices for high altitude flying. The Navy has developed a method of storing oxygen at high pressure in steel bottles from which the oxygen may safely be led into the aviator's mask without danger when the air pressure drops.

Aerial Passenger Line from New York to Atlantic City Being Organized

New York, N. Y.—Joseph M. Kahn, Vice-President and Treasurer of the Aero Transport Company recently stated that regular hydroaeroplane passenger and light freight service between New York and Atlantic City would be inaugurated on February 22. The round trip fare, according to Mr. Kahn, proprietor of the Aero Development Company, which company has recently acquired control of the Aero Transport Co., will be $50.

French Aviators Sail for Siberia

San Francisco.—Accompanying their own aeroplanes, aeroplane and food supplies, 100 French aviators and mechanics departed from San Francisco for Siberia recently. They were members of a party of 500 French aviators and troops which came here more than two months ago while on their way to the Siberian front. Three hundred departed Jan. 5.

The 200 remaining will return to France.

Australians Recommend Aeronautic Courses At Universities

Sydney.—The Sydney *Sun* advocates that aerial engineering, including practical flights, should be included in the curricula of universities, and urges the early return of Australian aviators from the various battle-fronts on which they have been operating in order to expedite commercial aeronautic progress in Australia.

Flies 200 Miles Standing On Wing

Hampton Roads, Va.—Ensign A. W. Gorton, aviator in the Hampton Roads Navy Aerial Mail Service, has won official recognition for his great courage in successfully holding open the throttle of a damaged mail seaplane through a 200-mile flight. At times it was necessary to grip the radiator to maintain his perilous position, and on one occasion the radiator cap came off, with the result that Ensign Gorton was scorched in the face. Nevertheless, for two hours and thirty minutes, until the completion of the 200-mile flight, Ensign Gorton "carried on."

Henry Woodhouse Lectures before American Geographical Society

That an American business man has offered to pay $50,000 for the privilege of being carried as mechanic in the first trans-Atlantic flight, was announced by Mr. Henry Woodhouse, Member of the Board of Governors of the Aero Club of America, during an address which he delivered before the American Geographical Society on February 11.

"This progressive business man," said Mr. Woodhouse, "happens to be experienced in gas engines and is anxious to have the privilege of attending to the motors of the first trans-Atlantic flyer. He has not authorized making his name public."

Mr. Woodhouse's subject was "The Trail of the Aeroplane." He reviewed the development of aircraft from, since the experiments made by the Romans and Chinese before Christ, and every important development in aeronautics, up to date.

He told of flights of allied aviators across the Great Atlas Range of Mountains of Northern

The Aero Club of America gave a banquet in honor of Captain Eddie Rickenbacker, the American Ace, who recently returned from France. Sitting, from left to right, are Major Gilles, Capt. Rickenbacker, Henry Woodhouse, Member Board of Governors of the Aero Club; Augustus Post, Secretary of the Aero Club. Some of the others prominent in the group are Jacques Boyriven, the French Ace; Lieut. P. Micelli, Lieut. Elsaser, Ensign A. W. Smith, Lieut. C. Weinstein, Rear Admiral Bradley A. Fiske, Lieut. M. Gilbert Whitman, Major H. Bubb, G. Douglas Wardrop, S. Cullinan, Col. T. Jefferson Thompson, and Evan J. David

Africa and across the Sahara Desert, across the Alps, the Macedonian and Asiatic Mountains, and the Andes.

"Caproni triplanes carrying sixteen passengers fly regularly over the Appenines," said Mr. Woodhouse, "an air line having been established to Florence.

"The flight of 28,900 feet of Major R. W. Schroeder, U.S.A., and of Captain Lang and Lieutenant Blower, British Royal Air Force, to 30,500 feet, have shown that man can fly over the highest mountains and that air lines across the Himalaya range are within the possibilities of the coming year. They may be established to establish faster inter-communication between the British forces on the Caspian Sea and Calcutta, Bombay and other important points in British India.

"Any aeroplane that could not fly higher than Pike's Peak did no service in the war zone."

Mr. Woodhouse spoke enthusiastically of the plans of Captain Bartlett's Arctic Expedition, which is to employ aeroplanes for exploration of the unknown Arctic regions.

He also stated that Great Britain has developed large dirigibles and that dirigibles capable of carrying 100 tons of useful load and of traveling 10,000 miles without stopping are being planned.

The lecture was illustrated with special films, showing the British passenger and aerial mail lines in operation.

Major T. W. Wrenn to Stay in Regular Army

Washington, D. C.—Major T. W. Wrenn, now on duty in Washington, has been ordered to report to Camp Meade to a board appointed to determine his fitness for a permanent appointment in the Regular Army.

Major Wrenn has for a considerable time been examining recruits in the Air Service at Washington. Major Wrenn's home is in New York.

Joy Rides In Army Aeroplanes By Civilians Not Permitted

The Director of Military Aeronautics has announced that civilians will not be permitted to make flights or take joy rides in Army aeroplanes without authority from the Secretary of War. Paragraph 1586 Army Regulations provides that:

"Flights in Air Service equipment for other than training or war purposes will be made only upon the express authority of the Chief of Air Service, and no person in the military service is authorized to permit other than the following to be carried as passengers in such equipment: Heads of executive and judicial branches of the Government, members of the Senate and House of Representatives, officers and enlisted men in the Army, Navy, and Marine Corps, and members and employees of the Air Service."

Gen. Kenly directs that no exceptions will be made to the above regulation by the Division of Military Aeronautics. Civilians who desire to take trips must first get authority from the Secretary of War before presenting themselves to the commanding officers of flying fields or the Division of Military Aeronautics with requests for flights. Applications for flights will not be forwarded to the Secretary of War through the Division of Military Aeronautics.

A. Leo Stevens Under Fire

Washington, D. C.—Captain Treat, Captain Fuller, Captain Saunders and Major A. Leo Stevens started on what was expected to be a most peaceful balloon flight recently, only to find themselves, after several hours, in the midst of a barrage of high explosive shells.

The party left Washington on February 12th, at 10 A. M., drifting in a northeasterly direction, passing Baltimore at 1:30 P. M. Later the balloon reached the Aberdeen Proving Grounds, where the large shells for the Army are tested. Suddenly heavy firing was heard and shells began to burst on all sides of the basket, causing it to be tossed from side to side as in a heavy barrage.

Orders were immediately given for increased altitude. Ballast was dropped overboard and the balloon rose to 5,000 feet, heading toward the Atlantic. A successful landing was made at Camp Columbia, 18 miles from Atlantic City.

General Menoher Receives Decorations

General Menoher recently received through the State Department, two medals from the French Government. One of them conferred the rank of Commander of the Legion of Honor, and the other was a Croix de Guerre with palm. The citations to accompany these medals have not yet been received.

Heads of A. E. F. Air Service Organizations

About the time of the signing of the Armistice, the American Air Service overseas was commanded by Major General Mason M. Patrick, Chief of Air Service, A. E. F., Headquarters, Tours. He had two chief assistants: Brig. Gen. William Mitchell, Assistant Chief of the Air Service, Army Group, or Zone of Advance, and Brig. Gen. Benjamin D. Foulois, M. A., Asst. Chief of the Air Service, Service of Supply.

On November 6th, the chief of the Air Service, First Army, was Col. Frank P. Lahm, J. M. A.; the Chief of the Air Service Second Army was Col. Thomas DeW. Milling, M. A.; when the Third Army Air Service was organized Brig. Gen. Mitchell took command and on January 8th, 1919, was stationed in Coblenz, Germany.

Col. Milling was chief A. S. 1st Army at Orquevaux, on January 8th, 1919, and Col. Lahm was chief of the A. S. 2d Army, at Toul.

Col. Charles deF. Chandler, J. M., Aeronaut was head of the American Balloon Service, A. E. F.

In Italy the Headquarters of the American Air Service was at Rome, where Major Robert Glendenning was in command.

In England the Headquarters Air Service, Base Section No. 3, was under the command of Col. C. R. Day.

Paris Headquarters were under the command of Lt. Col. H. Dunwoody.

Col. Aubrey Lippincott commanded the Air Service Repalcement Barracks at St. Maixent, where the complete organization and equipment of the squadrons was carried out, except the planes which were flown to the advance stations by the pilots from Orly, the Aviation Acceptance Park, commanded by Col. T. A. Baldwin.

Lt. Col. Hiram Bingham was in command of the 3d Army Instruction Center, at Issoudun, the largest flying school in the world, having 14 fields.

Col. W. G. Kilmer, J. M. A., was chief of Training, Hdqs. Tours, Lt. Col. E. V. Sumner was in charge of Air Service Production Center, No. 2 at Romorantin.

Col. Whitehead was chief of staff for the Air Service at G. H. Q. November 11, 1918.

Liberty Motor Test Flight Is Completed

Houston, Tex.—The Liberty motor test flight from Ellington Field to Detroit and return was completed recently when the aeroplane handled by Capt. L. J. Robinson and Lieut. A. A. Adams landed at the home field.

Capt. Robinson estimated the distance covered at between 4000 and 5000 miles and gave the flying time as 1650 minutes. The average speed was 110 miles an hour for the entire distance and the maximum 125 miles.

The trip was devoid of engine trouble.

The flyers left Ellington Field December 21.

Baker Makes Ruling As to Enlisted Men

Washington.—Secretary Baker recently submitted to the house a bill providing that enlisted men of the regular army who were discharged to accept commissions in the army during the war, shall be given the retired pay and allotments of master signal electricians when mustered out of the service. Secretary Baker said all of the enlisted men who were commissioned had performed valuable service and that the proposed reward was no more than a just recognition of their services.

War Department Warns Against Unauthorized Insignia

Washington, D. C.—Under the direction of the Secretary of War, circular instructions have been issued to post exchanges at military posts forbidding the sale of unauthorized insignia, such as service ribbons and gold and silver stars. Efforts are being made to induce stores located near cantonments and military posts to refrain from selling such insignia.

Colonel Thaw's Squadron Has Great Record

Lieut. Col. William Thaw assumed command of the Third Pursuit Group on August 1, 1918. Within a month this unit consisted of four flying squadrons and one park squadron, including what remained of the Lafayette Escadrille. The first active service of importance for this unit was in connection with the St. Mihiel drive. During the month of September and October alone these squadrons engaged in 165 combats and were officially credited with downing 52 planes. The figures for October show 99 combats with 40 victories. Of course there were many additional unrecorded victories, as well as the regular reconnaissance activities and bombing work of the Third Pursuit Group.

Divisional Insignia Worn By Casuals Returning Home

The Division of Military Aeronautics issues the following:

By order of the Secretary of War, officers and enlisted men returning from France as casuals for the purpose of discharge, will be permitted to wear insignia indicating the tactical division, Army corps, or Army with which they served overseas. This applies not only to those who are to be immediately discharged, but also to those retained in hospitals, pending discharge.

The first photograph to be published in America of the famous De Haviland 10, which is to be used in the London to Paris passenger service, to be established this Spring. The machine is equipped with two Rolls Royce motors, and has a maximum speed of 128 miles per hour

The AIRCRAFT TRADE REVIEW

Bartlett Hayward Co. Buys Hammered Piston Ring Co.

The Bartlett Hayward Company, of Baltimore, has purchased through the Fidelity Securities Company, of that city, the entire capital stock of the Hammered Piston Ring Company of America, whose plant is located on South 11th Street, Newark, N. J.

The Bartlett Hayward Company is a Baltimore concern, which manufactured munitions on a large scale and at the present time has almost unlimited capacity for the manufacturing of American Hammered Piston Rings.

They contemplate keeping the Newark plant in operation, but will take on the overflow from Newark; and all increases of business will be handled in one of their plants in Baltimore.

The active management of the business will remain in charge of Mr. C. F. Hockley, Vice-President and General Manager, who will make headquarters in Newark.

Navy May Use N C-1 for Trans-Atlantic Flight

Washington, D. C.—Commander John T. Towers, one of the foremost naval aviators in the service, has been ordered to duty "in charge of the development of plans and the assembly of material and personnel for the trans-Atlantic flight."

Plans for accomplishing this feat were fairly well under way last summer, but the necessity for conserving all material for purely military purposes did not permit the release of the necessary material for this purpose. It was proposed to start from Halifax, Nova Scotia, and it is assumed that this year's plans call for the same port of embarkation.

It is considered likely that the N C-1 will be used for this purpose. This boat recently carried fifty-one passengers, and its capacity for weight carrying makes it possible to load it with sufficient fuel, lubricants and supplies for the long flight. The ship is propelled by three Liberty motors and has sleeping compartments for three men. The crew consists of two or three pilots, three mechanics and a radio operator.

Smithsonian Institute to Hold Permanent Aircraft Progress Exhibit

Washington, D. C.—Charles D. Walcott, Secretary of the Smithsonian Institute, has requested an appropriation of $14,000 for heating equipment and repair on a metal building to the rear of the Institute, which was originally erected to house an exhibit of foreign aircraft for the benefit of the Signal Corps.

The exhibit will soon be opened to the public. It includes the latest type of aircraft motors and accessories developed during the war. The Bureau of Aircraft Production has been cooperating with the Smithsonian Institute in an endeavor to collect a comprehensive and complete exhibit.

United States Liquidation Commission Appointed

The Secretary of War has appointed a commission to liquidate America's indebtedness to the Allies for material, supplies, munitions, etc., and to dispose of movable and immovable property used by our forces in France and England.

Claims against Allied powers arising out of contracts made in the United States with the War Department will be settled and all types of foreign indebtedness liquidated. Mr. Chester W. Cuthell was recently designated by the Secretary of War for these duties. Hon. Edwin B. Parker of Houston, Texas, Hon. Henry F. Hollis of New Hampshire, Homer H. Johnson of Cleveland and Brigadier-General Chas. G. Dawes of Chicago are members of the commission.

Captain Sunsted's Boat Damaged in Launching

Newark, N. J.—The launching of Captain Sunsted's huge seaplane, on February 11, designed for the transatlantic flight, was marked by a slight accident, resulting in the damage of one end of the lower plane. Delay in getting a motor launch to tow the seaplane into the open waters of Newark Bay from its resting place on a huge float, caused Captain Sunsted to attempt to get off under his own power. The plane moved off the float successfully but upon hitting the water, the unequal speed of the motors, aided by the inshore wind caused her to turn diagonally toward shore. The motors were shut off, but not in time to prevent crashing into the end of a dock which extended one hundred feet into the bay. The repair of the damage will be accomplished without much difficulty and trials will be resumed within a few days.

It was stated that in the projected transatlantic flight, that Lieutenant Paul Micelli, an Army aviator, who received his first training in the French air service, will accompany Captain Sunsted as relief pilot. W. Harding and F. Baatz are reported as having been selected as mechanics.

Alfred Bartsch is Bosch Sales-Manager

Springfield, Mass.—Mr. Alfred H. Bartsch has been appointed General Sales and Advertising Manager of the New American Bosch Magneto Company.

Prior to America's entry in the War, Mr. Bartsch had been for more than seven years advertising manager of the Bosch Magneto Company, and for the past two years has represented a number of prominent firms in the automotive field as advertising and sales counsel.

Bureau of Standards on Solder for Aluminum

The Bureau of Standards Circular No. 78 discusses the use, serviceability, method of application, and composition of soldiers for aluminum. The information contained in the circular is the result of an investigation of commercial and other compositions of solder. It was found that soldered joints were subject to corrosion and are not recommended unless some form of protection is provided.

Naval Appropriation Bill Under Consideration

Washington, D. C.—The Naval Appropriation Bill H. R. 15539, reported in the House on February 1st carries appropriations totalling $745,000,000. Prior to the signing of the armistice, Secretary Daniels asked for $2,600,000,000, but, since that time reduced this figure to $975,000,000.

The present permanent authorized strength of the Navy calls for 350 men in the Naval Flying Corps. The Act of July 1, 1918, authorizes a temporary increase to 10,000 men. The bill now under consideration is not yet specific regarding increase in the permanent personnel authorized. Secretary Daniels does not recommend a permanent increase from the present authorization of 140,000 men for the entire Navy but a temporary increase to June 30, 1920, for 225,000.

The Bureau of Navigation recommends a temporary increase calling for a personnel of 350,000. The strength of the Navy on November 11, 1918, was 497,030 men and women. Whether the air personnel is to be reduced to the same proportion as the entire Naval Personnel is not known.

The appropriation for aviation last year was $220,383,119. The original recommendation for this year was $225,000,000. After the armistice officers in charge of aviation reduced this figure to $85,649,300. Secretary Daniels cut this figure to $36,000,000 and the committee, although feeling that aviation is a very important branch of the service, further reduced the recommendation to $25,000,000. The House further reduced this sum to $15,000,000, and added the proviso that none of this sum be expended for construction work on the naval aircraft factory.

Material Ordered According to New Army Program

Washington, D. C.—The Bureau of Purchase, Storage and Traffic is letting contracts for supplies needed in connection with the reduced Army program.

The Poole Engine and Machine Company has received a $145,000 contract for 37 mm. semi-automatic aeroplane cannon.

The A. O. Smith Corporation of Milwaukee has a contract for drop bombs.

The Holt Manufacturing Company is making caterpillar trailers for 4.7 inch anti-aircraft guns.

The Grant Motor Car Company is working on an anti-aircraft trailer contract amounting to more than $50,000.

The Remington Typewriter Company has a small contract for bomb release mechanism.

The Globe Metal & Stamping Company has a $7,500 contract for adapters for Browning machine guns to anti-aircraft service.

The Marlin-Rockwell Corporation of New Haven, Conn., has a $10,000 contract for hammer spring compressors for Marlin Aeroplane Machine guns.

Repair part orders ranging from small amounts to $9,000 have been received by the following companies: Standard Aero Corporation of Elizabeth, N. J., Wright-Martin Aircraft Company of New Brunswick, N. J., Ford Motor Company of Detroit, Mich., Ohio Rubber Company of Cleveland, and the Goodyear Tire & Rubber Company of Akron, Ohio.

The Aeromarine Model 40-T Flying Boat equipped with a 100 H.P. Curtiss OX engine

Hon. Albert S. Burleson, Postmaster General

St. Louis Establishes Aero Landing Place

St. Louis, Mo.—If plans already under way are carried out, St. Louis will have an aerial landing place, intended not only for mail and government planes but for sportsmen aviators. $25,000 is being made available for grading the field.

"Aviators flying from Detroit or Chicago or Kansas City," said Mayor Kiel of St. Louis, "knowing that St. Louis has a fully equipped landing field, will come here. St. Louis will become a sort of transcontinental aeroplane terminus."

Plan for Aerial Service from Australia to London

Consul Henry P. Starrett, at Adelaide, Australia, reports:

Prominent business men of Sydney, Melbourne, and Adelaide, under the leadership of Mr. Reginald Lloyd of London have formed a company with £10,000 ($48,665) paid up capital for the purpose of developing an aerial route for mail and passenger service between Australia and London.

The purpose of the company is to explore the proposed route for landing sites which are to be approximately 300 miles apart. The route is to be from Sydney or Melbourne direct to Port Darwin in the northern territory of Australia, from which point there will be a 300-mile sea trip across to the island of Timor in the Dutch East Indies, thence from island to island through Java and Sumatra to Singapore and Calcutta, across India to Karachi, thence to Bagdad and Port Said, from which latter point the choice of several developed aerial routes to London are available.

Next month Mr. Lloyd will lead a surveying party from Australia through the Dutch East Indies, the Malay States, India, and Mesopotamia for the purpose of locating landing sites and to arrange for their lease or purchase. The organization of the present company is merely to provide for the expenses of this routing party. After the completion of this survey it is proposed to finance a company in London to operate the aerial service to Austrial which contemplates a complete journey in 150 hours between London and Sydney.

Le Pere Planes at Bolling Field

Washington.—Two of the latest type American-made scout planes, the Le Pere, have arrived at Bolling Field for test flights. These are the first two planes of this particular model made in the United States and were designed for use of American aviators at the front.

The aeroplanes are camouflaged green, blue and white, and have 12-cylinder Liberty engines. The planes, it was stated, weigh approximately 3500 lbs., with a wing spread of 24 ft. They can climb 22,000 ft. and attain a speed rate of 135 m. p. h.

Personal Pars

Captain H. E. Westmoreland, who has been adjutant of the Air Service Replacement Concentration Barracks No. 3 at St. Maxient, France, for the past eighteen months, is back in the United States. He was for a number of years Southwestern manager for the McQuay-Norris Mfg. Company, St. Louis, with headquarters in Dallas. His future plans are not yet determined.

Elmer Sperry, inventer of the gyroscope, will address the March meeting of the Detroit Section Society of Automotive Engineers.

Flying Circus at Rockwell Field

San Diego, Cal.—Rockwell Field staged a most pretentious "flying circuit" for the amusement of the San Diego populace. The events on the program not only included all manner of extended formation flights, aerial combats, hair-raising stunts, and aeroplane races, but such features as the bombing and destruction of a large model "German Castle," various vaudeville acts presented by individual units of the command and band concerts by eight military bands.

The day's program began at noon and ended at midnight. Several aviators just returned from overseas participated in the events of the day. The camp was thrown open to visitors and a huge success was scored.

Cost per mile, overhead, $.4624; cost per mile, flying, $.2374; cost per mile, maintenance, $.6551.

*Repairs and accessories plane No. 1 include overhauling of damaged motor.

Note—Cost per mile, maintenance, on November report should read $.3277 instead of $.4007.

OTTO PRAEGER, Second Assistant Postmaster General.

THE SUNDSTEDT-HANNEVIG SEAPLANE

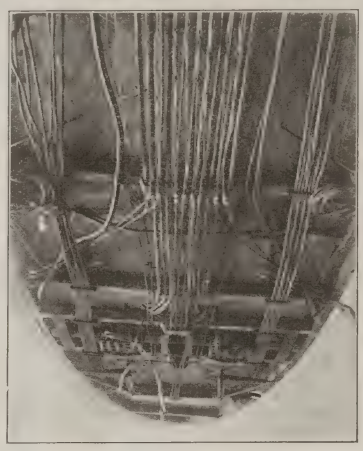
At the plant of the Wittemann-Lewis Aircraft Co., probably one of the largest seaplanes in the United States has been constructed by the prominent Swedish aviator, Capt. Hugo Sundstedt, and the well-known Norwegian financier, shipbuilder and shipowner, Mr. Christoffer Hannevig.

Capt. Sundstedt is one of the pioneers in aviation, having flown since 1900. In July, 1914, just before the war broke out, he made a non-stop flight from Buc, near Paris, France, to Stockholm, of about 1200 miles in a Henry Farman biplane in 13 hours and 20 minutes. During the war Capt. Sundstedt had been about two years in France and received several decorations. About two years ago he left France for the United States with the purpose of building an aeroplane for a transatlantic flight.

The Sunstedt-Hannevig seaplane has been designed for the specific purpose of long distance flying over the sea. In general, it has been designed with an extra heavy substantial construction, particularly on those parts subjected to the greatest amount of strain during flight and at landings, such as pontoons, wings, and the entire rigging.

In the design, however, only proved aerodynamical principles have been embodied, assuring a positively efficient machine, and Capt. Sunstedt has made a large number of improvements in structural details, affording the utmost strength and lightness of construction.

The seaplane is equipped for two pilots and two passengers in the cabin of the fuselage.



General Dimensions

Span, upper plane	100′-0″
Span, lower plane	71′-6″
Wing chord, lower plane	8′-0″
Wing chord, upper plane	8′-0″
Gap between wings	8′-72″
Length of machine over all	50′-6″
Height of machine over all	17′-7″
Dihedral angle, lower plane	2°
Wing curve	U. S. A. No. 5
Total lifting surface	1537 sq. ft.
Rudder area	22 sq. ft.
Elevator area	54 sq. ft.
Weight	10,000 lbs.
Loading per H.P.	25 lbs.
Loading per sq. ft.	6 lbs.
Speed, estimated, full load	80 m.p.h.
Climbing speed, estimated	3000 ft. in 10 min.
Horsepower, total	440

Pontoons

The pontoons are of special Sundstedt design, embodying the highest developed features of streamline and follow the most accepted construction practice. They are made of Capt. A. P. Lundin's special three-ply Balsa wood veneer, covered with linen, and are each divided into eight watertight compartments, painted and varnished with torpedo gray enamel. They are 32′-0″ long, spaced 16′-0″ apart from centers, and are light in weight, being 400 pounds apiece, including fittings.

Each pontoon is equipped with an emergency food locker accessible from the deck by means of a handhole.

The underside of fuselage showing control connections on the Sunstedt-Hannevig Seaplane. It is covered by an aluminum cowling

The pontoons are braced to the fuselage and wings by a series of steel tubing struts with Balsa wood streamline fairing. These tubes are of large diameter and fit into sockets mounted on the pontoons and wing spars. The entire assembly is amply braced by steel cables and tubing connecting struts.

Fuselage

The fuselage is of streamline design, and is flat sided in order to provide sufficient vertical surface necessary for good directional stability. It has a curved streamline bottom and hood running fore and aft. The construction is of white ash and spruce, consisting of four longerons and ash and spruce compression struts fastened thereto with light universal steel fittings, to which are also fastened and connected diagonally the solid steel brace wires and turnbuckles.

The front end of the fuselage is fitted up much after the style of a closed motor car, with comfortable upholstered seats for the pilots and passengers. This cabin is accessible by a door on each side at the rear end of the cabin. A very complete field of vision is obtained through a series of glass windows around the front of the pilots' seats, forming a recess in the upper deck forward of the windows.

Directly behind this cabin, and balancing with the center of pressure is the main gasoline tank, with a capacity of 750 gallons, sufficient for 22 hours of full speed flying, and to the rearward of this is the adjustable open trussing, with a detachable hood and covering for access and inspection.

The forward section is covered with a thin three-ply mahogany veneer up to the rear of the cabin doors, and aft of these, it is covered with linen, doped, painted and varnished.

Control

The control system operates on the standard wheel and rudder bar method, and is of special Sundstedt design, whereby all cables are located beneath the floor, leaving a clean control column and rudder bar without any wires in the way of the passengers or pilots. Dual control is fitted, side by side, directly connected, so that the machine can be controlled by either pilot at will.

All engine controls and switches are located on the dashboard, operative from both seats.

Instruments

A substantial dashboard is fitted in front of the pilots' seat in a plainly visible position, and is equipped with tachometers for both motors, clock, altimeter, speedometer, radiator thermometers, oil pressure gauges, shut off valves, ignition switches, and so forth, which are located in within easy reach of the pilot.

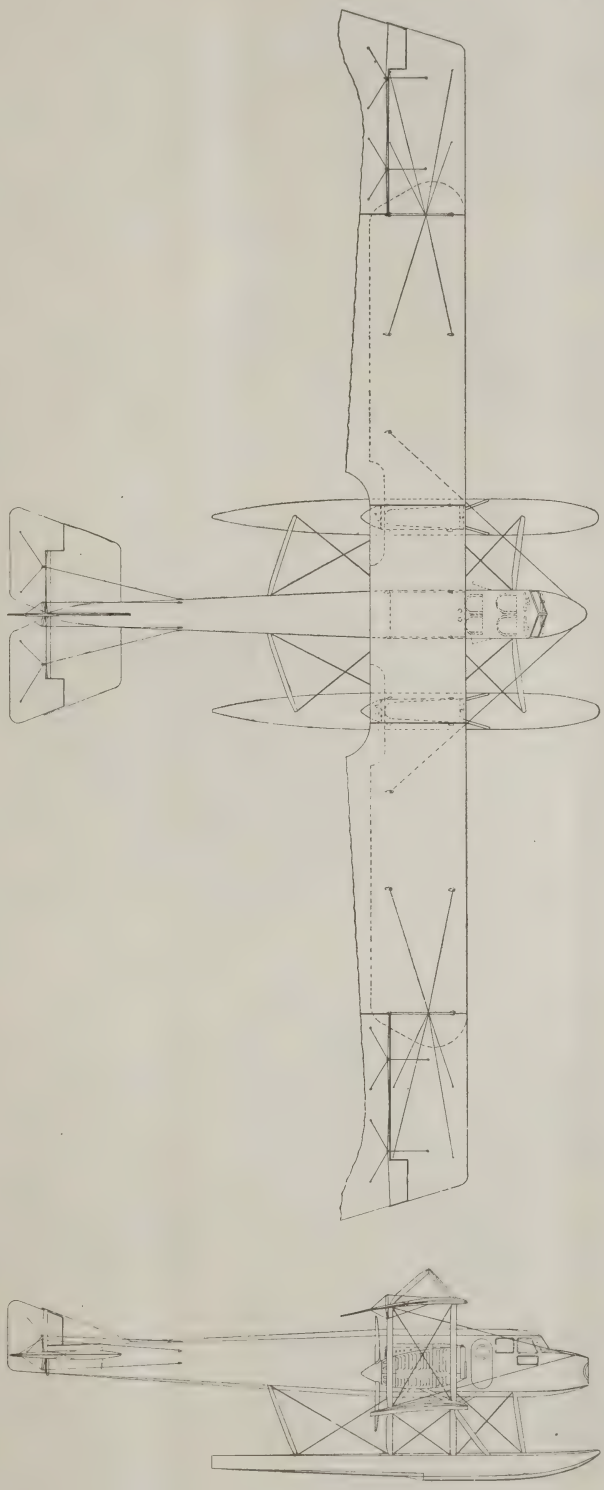
Power Equipment

The power plant consists of two Hall-Scott Model "L-6" H.P. engines, directly connected to two bladed pusher propellers. Each are mounted on a specially constructed bed by the Vee method of interplane struts, with the engine beds, housings, and radiators all securely braced to the wings, pontoons and fuselage.

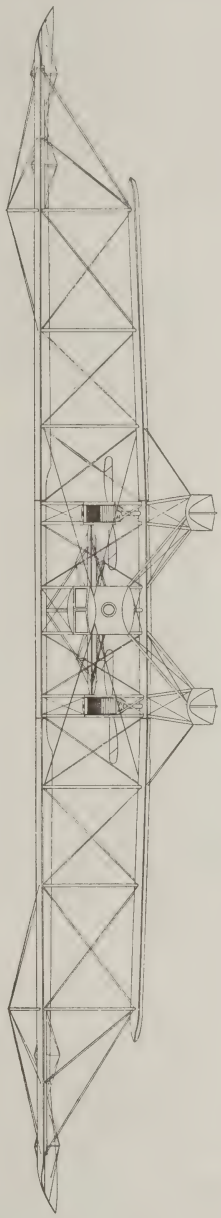
The engines are supplied with gasoline by turbine driven Miller gasoline pumps which maintain a pressure of 3 lbs. in a special reservoir of the pump itself, under automatic adjustment, and eliminating all of the difficulties and dangers of the gravity and pressure feed systems. These pumps are regulated from the cabin and within easy reach of the pilots.

Wings

The wings are built up of five sections in the top plane and three in the lower. The center section of both the upper and lower planes are 18′-10″ long, and so designed that the pontoons, the power plant, and the fuselage can all be assembled completely before adding the remaining outer wing sections, thereby taking up a minimum amount of space in assembly during manufacture.



The main spars are of laminated built up section, serving to give a very high strength and exceptionally light construction of a combined I-beam and a box beam section.



The upper wing has a chord of 10′-0″ at near the junction to the center section, and narrows down to 8′-6″ at the inside of the aileron cutout. Of this, 8′-0″ is well constructed web form of rib, while beyond this distance the cap-strips are

SEAPLANE

Scale of feet

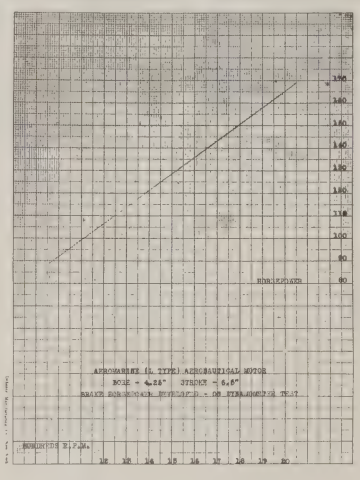
THE AEROMARINE TYPE L 6-CYLINDER AERO MOTOR

THE Aeromarine Plane and Motor Company, of Keyport, N. J., have supplied us with the following data concerning their Type L. 6-Cylinder aero-motor.

General Description

This motor is a six-cylinder, four-cycle, water cooled valve in the head type..

Bore, 4.25 inches. Stroke, 6.5 inches. Weight, 375 lbs. With electric starter and generator, 405 lbs. Rated horsepower, 130 at 1625 R.P.M.



This motor was designed and has been developed in all its stages with the sole object of producing a power plant suitable for training and sporting machines. Simplicity, accessibility and durability, without undue weight, have been the objectives in the design of this unit.

Crank Case and Cylinders

The main portion of the crankcase and cylinder jackets are integrally cast of aluminum alloy. This type of design eliminates a multitude of bolts, screws and fittings, and as well gives an extremely rigid structure. The cylinder sleeves are alloy steel forgings, machined all over, to give a uniform wall thickness. After machining, the sleeves are heat treated, and the working surfaces ground. The outside of these sleeves are in direct contact with the cooling water over their entire surface. The cylinder head gasket, of copper and asbestos, makes a tight joint against the top flange of each cylinder sleeve, the water joint at the bottom of each sleeve is by individual cork gasket, which allows freedom for expansion, and at the same time makes a perfectly satisfactory joint.

Cylinder Head and Valve Gear

The cylinder head and valve gear form a complete self-contained unit, which can be removed from the motor in a few minutes, allowing inspection of the valve combustion chamber and making it possible to remove the carbon or grind the valves within the very shortest possible time. The removing and replacement of this head may be accomplished without retiming the motor, due to a special arrangement of the splined shaft which drives the camshaft gear. The head is of aluminum alloy with gray iron valve seats cast in position. The combustion chambers are machined. The water cooling of the spark plugs, exhaust valve guides and valve seats is exceptionally complete. The cams and rollers are housed in, precluding possibility of oil reaching the combustion chambers through valve stem guides. There are four valves for each cylinder, two exhaust and two inlet. A special design of valve gear, embodying flat multiple leaf valve springs, effects a great reduction in length and weight of valves and valve levers, and also reduces the over-all height of the motor. Each valve spring actuates two valves. By a special design of the valve adjusting screw, a rolling contact is obtained between it and the end of the valve, thus eliminating the possibility of any side motion being transmitted from the valve levers to the valve stem. There is an oil return passage from each end of the cylinder head to the crank sump. The whole valve gear is enclosed in a quickly detachable aluminum cover, so that when the motor is in operation, there are no moving parts visible and the possibility of a pilot being annoyed by oil from the valve gear is entirely eliminated. The camshaft is hollow with integral cams and is driven by bevel gears and vertical shaft from the power delivery end of the motor.

Oil System

This motor is of the dry sump type, a dual pump being used to deliver the oil pressure to the working parts and to draw the surplus oil from under the sump, discharging the same into the auxiliary reservoir. This system avoids sooting of plugs and excessive oiling in the alternate ends of the motor as the aeroplane glides or climbs. It has a further advantage in that the oil in its passage to and from the auxiliary tank is cooled. All bearing surfaces in the motor, except valve stem guides, lubricate by pressure fed oil.

Crank Shaft

This is an alloy steel drop forging, heat treated, machined all over and dynamically balanced. It is of three main bearing type with additional propeller bearing. The bearings are of liberal size, the crank pins being 2½ inches in diameter by 2⅝ inches in length.

Pistons

These are of aluminum alloy, ribbed under head, and are fitted with two sealing rings above piston pin and an oil scraper ring below. The piston pin oscillates directly in piston pin bosses.

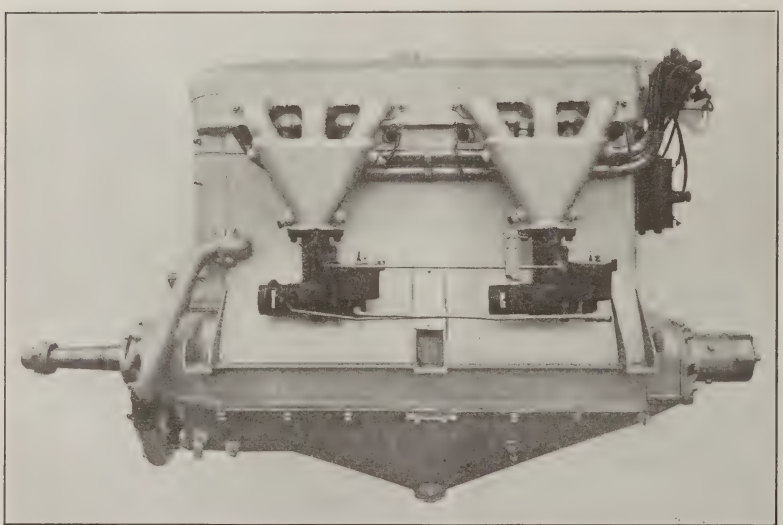
Connecting Rods

The connecting rods are alloy steel drop forgings, heat treated and machined all over, are of "I" beam type with four-bolt type cap. High class Babbitt metal is used, and is tinned directly into the rod.

Ignition

The ignition is by double Delco instruments driven directly from the end of cam shaft. There are two spark plugs in each cylinder.

Starter



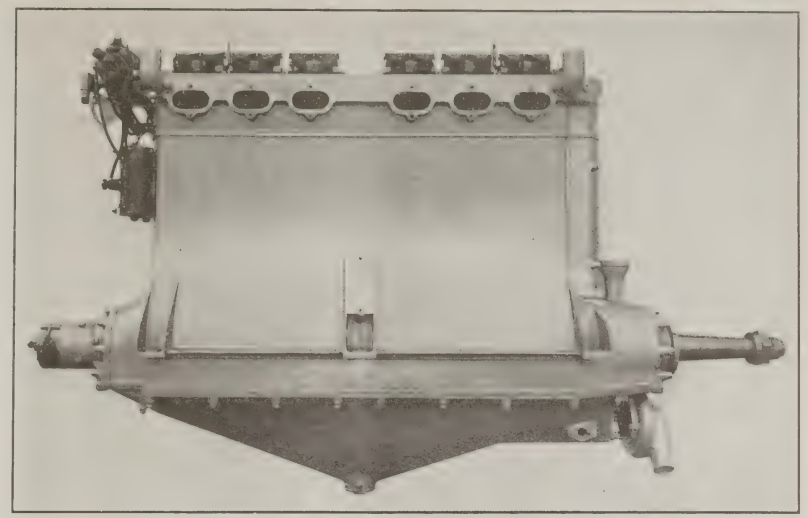
A Bijour electric motor starter is arranged to drive the motor through the rear end of the crankshaft, by means of a special automatic engagement and planitary reducing gear which has a ratio 56 to 1.

Generator

The Bijour generator is driven from the rear end of the camshaft. The motor and generator are built into the design in a neat and efficient manner.

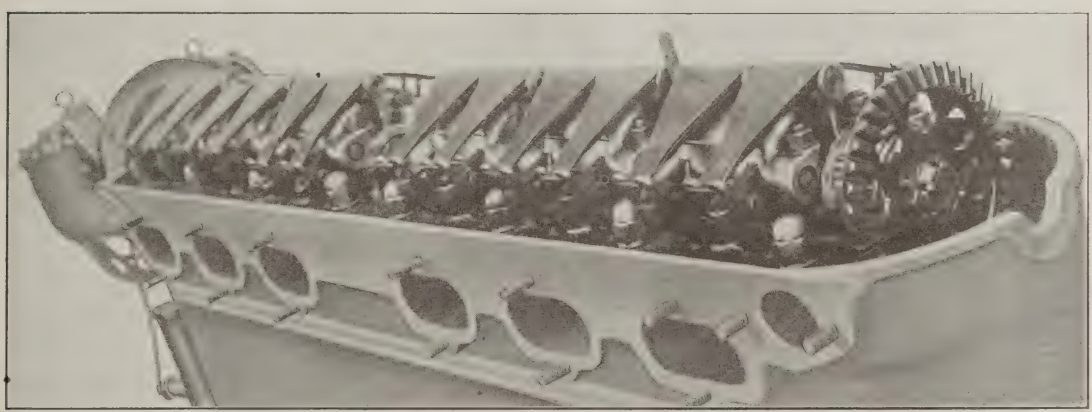
Carburetor

Two carburetors are used to supply the six cylinders and are now arranged on the side of the



Intake side Type L Aeromarine 6-cylinder engine

motor above the beds as shown in the accompanying photographs. It is considered possible that a dual carburetor may be placed back of and behind and below the motor with a dual feed pipe in the event that it is desirous to use a gravity feed.



This motor has been run to speeds in excess of 2500 R.P.M. for some considerable period of time, and even at this excessive speed, the peak of the power curve had not been reached. (See chart.)

Fuel Consumption

Tests extending over a period of more than 100 hours indicate that the fuel consumption of this motor is, approximately, 495 pounds per H.P.

Exhaust side Type L Aeromarine 6-cylinder engine

The cylinder head and valve gear form a complete unit on the Type L Aeromarine 6-cylinder engine

CITED FOR DISTINGUISHED SERVICE

THE commander in chief, in the name of the President, has awarded the distinguished service cross to the following-named officers and soldiers for the acts of extraordinary heroism described after their names:

First Lieut. Howard T. Fleeson, Signal Corps observer, 12st Aero Squadron. For the following act of extraordinary heroism in action near Buzancy, France, October 30, 1918. Lieut. Fleeson is awarded a bronze oak leaf, to be worn on the distinguished-service cross, awarded him October 3, 1918. This officer accompanied a formation of nine planes on a photographic mission in German territory, six planes turned back before reaching the enemy line, and the remaining three were attacked by 18 Fokker-type planes when they had penetrated 12 kilometers into the enemy country. After his two companions, whom he tried to assist, were shot down, Lieut. Fleeson fought his way back to his own lines, destroying two enemy planes in the combat. Home address, W. H. Fleeson, brother, Sterling, Kans.

First Lieut. Hugh D. Broomfield (deceased), pilot (Air Service). For extraordinary heroism in action near Cunel, France, October 21, 1918. Responding to an urgent request for a plane to penetrate the enemy line to ascertain whether or not the enemy was preparing a counter attack, Lieut. Broomfield immediately volunteered for the mission. Obliged to fly at a very low altitude on account of the unfavorable weather conditions, he was under terrific fire of the enemy at all times, but by skillful dodging he managed to cross the enemy lines. Next of kin, Thomas Broomfield, father, 527 Tacoma Avenue, Portland, Ore.

Second Lieut. Clinton Jones, Air Service (pilot), 22d Aero Squadron. For the following act of extraordinary heroism in action near St. Mihiel, France, October 10, 1918. Lieut. Jones was a member of a patrol which succeeded in hedging a fast enemy biplane. Approaching the enemy plane Lieut. Jones signaled the enemy to give up and land. The reply was a burst of machine-gun fire, which cut his wind shield and set fire to his plane. Lieut. Jones then closed in and shot the German pilot and sent the plane crashing to the ground. He landed his own plane and extinguished the flames. Home address, Mrs. Clinton Jones, mother, 2617 Buchanan Street, San Francisco, Calif.

Capt. Hamilton Coolidge, deceased, 94th Aero Squadron. For extraordinary heroism in action near Grandpre, France, October 27, 1918. Leading a protection patrol, Capt. Coolidge went to the assistance of two observation planes which were being attacked by six German machines. Observing this maneuver, the enemy sent up a terrific barrage from antiaircraft guns on the ground. Disregarding the extreme danger, Capt. Coolidge dived straight into the barrage and his plane was struck and sent down in flames. Next of kin, J. R. Coolidge, father, 10 West Hill Place, Boston, Mass.

First Lieut. William H. Vail, Air Service, pilot, 95th Aero Squadron. For extraordinary heroism in action at Stenay, France, November 6, 1918. Lieut. Vail, while on patrol, engaged four hostile pursuit planes which were about to attack an accompanying plane. Almost immediately he was attacked by five more enemy planes, all of which he continued to fight until he was severely wounded and his plane disabled. He glided to the ground, abandoning the flight only when his machine fell to pieces near the ground. Home address, Mrs. Fred E. Vail, mother, 1535 South Paulina Street, Chicago, Ill.

Capt. Edward V. Rickenbacker, Air Service, 94th Aero Squadron. For the following act of extraordinary heroism in action near Billy, France, September 25, 1918, Capt. Rickenbacker is awarded an additional bar to be worn on the distinguished-service cross awarded him October 16, 1918. While on voluntary patrol over the lines, Capt. Rickenbacker attacked seven enemy planes (five, type Fokker, protecting two, type Halberstadt). Disregarding the odds against him, he dived on them and shot down one of the Fokkers out of control. He then attacked one of the Halberstadts and sent it down also. Home address, Mrs. William Rickenbacker, 1334 East Livingstone Avenue, Columbus, Ohio.

Second Lieut. Glen A. Preston, Field Artillery observer, 99th Aero Observation Squadron. For extraordinary heroism in action near Andevanne, France, October 29, 1918. Becoming separated from his protecting planes while on a photographic mission, Lieut. Preston continued alone, and, although he was attacked by seven enemy planes, type Fokker, he drove them off and secured numerous photographs. For the following act of extraordinary heroism in action October 30, 1918, Lieut. Preston is awarded one bar to be worn with his ditinguished-service cross. Lieut. Preston successfully accomplished his mission in spite of encounters with four separate enemy formations, one of 38 machines, another of 6, type Pfalz, another of 7, type Fokker, and a formation of biplane planes. He shot down one of the enemy and returned with valuable information. Home address, Mrs. Perry C. Davidson, mother, Howe, Ind.

MILITARY AEROSTATICS

By LIEUT. H. K. BLACK, R. F. C., C. F. A.

Free Ballooning

(*Continued from page* 811)

EVER since war broke out practically all the free ballooning which has been done has been for the purpose of training military and naval balloon pilots. The free balloon flights and parachute drops of the county fairs and the captive balloon of the amusement park and exposition have disappeared under the stress of military necessity.

With the return of peace, however, free ballooning will no doubt come into its own again, as the beginning of commercial aeronautices. It is the opinion of most people who should know, that the next decade will be the decade of commercial aeronautics, and that the next ten years will see as great or greater advancement in commercial aeronautics as the past ten years has seen in the advancement of wireless. Balloons and more particularly dirigibles will play a very large part in this advancement. Free ballooning will no doubt be revived to a great extent as a sporting proposition and as an aid to science. Therefore, a few points of how it is carried out may be of interest to the amateur aeronaut as well as to the layman.

To begin with, a suitable flying field from which to make an ascent is necessary. It should be sheltered without being cramped; sheltered to facilitate inflation and to eliminate the necessity of a larger crew to handle the balloon in a wind; uncramped so that the balloon may rise without danger of striking nearby objects, such as buildings, smoke stacks, trees, etc. Electric, or in fact any wires are a particular abomination to a flying field. If a hangar or building sufficiently large to house the balloon is available, inflation may, of course be carried out at leisure, but facilities, such as these, are more or less rare, so we will take into consideration only the outdoor flying field.

A smooth platform is greatly to be desired. A cement one is specially good, but it must be kept very clean, as small pieces of grit play the very deuce with a balloon envelope. Proximity to the gas supply is, of course, essential.

About a hundred sand bags, each filled with about fifty pounds of fine, loose sand and a filling hose will be necessary. The filling hose should be at least ten inches in diameter. It is made of canvas treated with rubber solution and is of low permeability. The envelope of the balloon is unrolled and laid out in a circle. The appendix or inflation sleeve is attached and the envelope pulled over until the valve hole is directly over the appendix, which can be seen through it. Care must be taken, however, when "pulling the envelope over" that strain is only applied at the seams and that the envelope is pulled firmly but without jerking—otherwise the fabric will tear.

The envelope at the point where the appendix is attached is propped up off the ground by three or four sand bags with the appendix running between them. The reason for this is that when inflation commences the gas must have free passage into the balloon. When the envelope has been pulled over and folded evenly in a circle, the net is pulled over the envelope. The net is made of light cordage, the meshes being fifteen to eighteen inches in diameter. It covers the entire balloon, being fastened to the valve at the very top of the envelope. From the net the basket is suspended and so to insure evenness in riding and ease in manipulation, great care must be taken that the net be put on evenly. Attention to this point is necessary from the time the net is pulled over the envelope until the inflation is nearly complete. Failure to put the net on evenly imposes additional strain on some parts of it, causes the appendix at the bottom to be off to one side, the basket does not ride evenly, the maneuverability is increasingly difficult, and the safety of the flight decreased. Before the net is pulled over, the valve and rip cords which enter the balloon through the appendix, are pulled well into the envelope, the red one, being the rip cord, fastened securely to the lug of the rip panel and the white valve cord to the spider of the valve. The valve is adjusted, tested, properly lubricated to make it gas tight, and fastened in its place by its bolts. The net is then tied around the valve. The lower part of the net should be pulled well out from the envelope and a few sand bags hooked on to it. The balloon is now ready for inflation.

The inflation hose may be connected with the appendix by its thimble, but before it is attached to the gas supply the gas should be turned on slowly to blow out the pipes and to be sure that there is no air remaining in them. The inflation hose is then attached to the source of supply and the gas turned on slowly. It is inadvisable to turn on the full head of gas for the few first minutes because it is in those few first minutes that the opportunity for adjusting and straightening the net occurs. When the net has been straightened and enough gas has entered the balloon to raise the valve off the ground, the flow may be increased gradually to full pressure. Care must be taken, however, that the flow is not enough to get ahead of the crew, for it will be found as the balloon rises like a yeasty pancake that the net with its attached sand bags will tend to hold down the balloon. As more gas enters, it will be necessary to add more sand bags to the net, and with a large flow of gas quick work will be

The new U-Type dirigibles packed and ready for shipment

necessary. The crew must keep letting each sand bag down another mesh, so the balloon may rise. It is also necessary that each sand bag be let down the same amount, otherwise the net will be crooked. A bit of judgment is required to know just how tight the balloon should be kept, for if the inflation is done in a wind, and the sand bags are let down too far, the wind will tend to get underneath and blow the envelope about and maybe overturn the whole business. On the other hand, if the sand bags are not let down far enough, the increasing pressure on the material of the balloon will retard the flow of gas or even stop it. If the flow of gas, however, be very strong, it will lift the sand bags right off the ground or if their weight be too much, burst the balloon. Experience alone will teach one how tight the balloon should be kept.

As the balloon rises above the equator, the lower half will fill increasingly quick, and it is then that the work of shifting sand bags must become more snappy. In a wind at this juncture also, considerable care must be taken that the balloon is heavily enough sand bagged to keep it on the ground. Just before it is fully inflated, the gas flow should be reduced somewhat, and while the balloon should be entirely filled with gas, the gas must be turned off instantly when this occurs. The filling hose should be disconnected and the appendix tied loosely with a bit of tape. In the meantime, the basket should have been rigged, the aneroid barometer adjusted, the compass and the barograph placed in position, the ballast pocket filled, maps and other impediments packed in their respective places. The drag rope should have been coiled, attached to the basket suspension, and hung on the basket. The anchor likewise. In the bottom of the basket there should be from six to ten sand bags as ballast. The basket is then carried to its position underneath the balloon and fastened carefully to the net by its suspensions. This should be supervised by some responsible party. In the meantime, sand bags are hung on the lowest mesh of the net. Now, they are one by one transferred from there to the short basket suspensions, and from thence to the long basket suspensions. As this is being done the balloon gradually rises, till when the sand bags have been transferred from the long basket suspensions to rings on the exterior of the basket, the balloon has assumed a position a few feet above the basket and in flight position.

Here is one on the energetic Colonel C. G. Brant of the Division of Military Aeronautics. He went up for his first balloon trip recently and thought he could "get away with it." But a strange plane came along and snapped him. Here is how it came out. The air isn't safe any more. Those pesky magazine photographers are ubiquitous

The pilot, his aide and the passengers now take their place in the basket and approximately their combined weight in sand bags is removed from the exterior rings of the basket. Bag after bag is taken off until, as is generally the case, they are all removed. Then a rather delicate and important procedure is necessary. This is known as "weighing off," and it consists in removing sand from the interior of the basket until the lift of the balloon is just equal to the weight of itself and its passengers. Theoretically, this means that if the basket is on the ground it will stay there, but one might lift the entire balloon off the ground with one finger and if it is raised six inches from the ground it will remain in that position. Then the balloon is said to be "balanced."

As it very seldom is the case that there is no wind, the crew must retain their hold on the balloon.

The expenditure of one handful of sand will cause the balloon to rise. However, as it is generally advisable to make a fairly steep ascent, the pilot spills overboard a few pounds of sand, shouts "Let go," and breaks the tape which is holding the appendix closed, the crew releases the balloon and it rises at a very steep angle dependent, of course, on the strength of the wind.

A detailed description of a free balloon trip from the time the balloon leaves the ground until it lands and is packed up ready for its return to its station will appear in an early issue.

Balloon crew at the manifold's opening cocks, allowing gas to flow from cylinders into the feeding tube

Balloon in the hangar, with crew on the tube, being inflated with gas. The sand bags are in place along the tube as a precautionary measure

IMPORTANCE OF HIGH THERMAL EFFICIENCY IN AEROPLANE ENGINE DESIGN AND CONSTRUCTION

By CHARLES W. BURRAGE*

IN any engine it is desirable to obtain as much useful power from a given amount of fuel as possible, but in practically all of these machines the question of efficiency is purely a matter of expense—the cheaper one having the advantage over its competitor. In an aeroplane engine, however, not only is it important to have the engine operate as cheaply as possible, but it must also be *efficient* in order to have the quantity of fuel, and therefore the weight carried, a minimum. This has been particularly important in military machines, where long non-stop excursions into the enemy's country, together with the return flight, has been of the greatest advantage. But even in times of peace it is hardly conceivable that fuel stations will be established so thickly over the entire world that a machine can land near one of them in a half hour's notice.

One of the greatest advantages of the aeroplane is its ability to navigate over any kind of surface that the earth presents, as it needs no track nor roadway, and there will always be large areas where landings will be extremely difficult or impossible. Even if this were not so, the less fuel required for a given distance, the less weight would be taken up and the more freight or passengers could be carried. This question of economy is very prominent among the problems of trans-Atlantic flight, where it is desirable to fly from one continent to the other without any stop to take on fuel.

While it is perfectly obvious that a plane fitted with an engine having a low fuel consumption, etc., can travel further with the same weight of fuel than if fitted with one less economical, yet the extent of the saving is not always apparent. Fig. 1 has been prepared with the object of showing graphically the differences between a few representative aeroplane power plants. Weight per brake horsepower has been ploted as ordinates against duration of flight in hours as abscissae. On the ordinate of zero time has been plotted the weight of the engine plus radiator, water, piping; etc., or what is known as the metal weight of the engine. Distances on succeeding ordinates represent metal weight plus the weight of fuel, lubricant and tankage for the time considered. Using these co-ordinates, all engines having the same fuel and oil economy will be represented by parallel lines, their relative positions being governed by the metal weight of the engine alone, so that the engine with the lighter metal weight is lighter under all conditions of flight.

With engines of different metal weights, however, the one with the lower fuel consumption will be the lightest for long flights no matter what its original weight per H.P., provided, of course, the distance considered is great enough. This is shown on the plot by line *M* crossing *G* after a little more than an hour's flight. The former is the weight per H.P. line of the German Maybach engine, which has a metal weight of 3.31 lbs. per B.H.P., while the latter is that of the Gnome, which is lighter in metal weight (2.8). But when fueled for a six hours' flight, the Gnome weighs 9 lbs. per B.H.P., while the Maybach has a weight of only 6.72 lbs. per B.H.P. Thus it is seen that the engine of low metal weight and high fuel economy is lighter only for comparatively short flights, or at the end of longer ones. Accordingly, if the addition of metal weight improved economy, it would pay to do so on an engine designed for long endurance flights. But on the other hand, unless the improved economy was quite marked, nothing would have been gained. This is shown by a comparison of lines *M* and *A*—the latter of which is the line obtained from the operating characteristics of the Liberty 12, Model A. The economy of the Maybach is slightly better than the Liberty, but in order to place them on an equal weight basis, the respective planes would have to be equipped for more than 17 hours' flight, and for all times when the plane had a quantity less than sufficient for this length of time, the Liberty would be superior because of its less metal weight.

If all the engines considered had the same horse-power, vertical distances between any two points on the lines multiplied by the horse-power would give the difference in weight of the two power plants with accessories and supplies for the distance under consideration. Similarly, horizontal distances between any two lines indicate the difference in cruising radius for the same total weight. In plotting the lines *A, B, C* a plane has been assumed that has a maximum capacity for fuel, etc., of 10,000 lbs. and uses for motive power engines totaling 1,000 B. H. P.

In the case of engine *A* (the Liberty 12) the metal weight including the cooling system is 2.8 lbs. per B.H.P., the actual value, and the thermal efficiency 25%. Engines *B* and *C*, however, have been figured with a weight of but 2 lbs. per B.H.P., a value that has already been obtained by one or two manufacturers. The thermal efficiency of engine *B* has been taken as 30%, a value certainly obtainable, and that for *C* as 38%, a quantity that the writer believes possible of attainment.

Using these values the following results have been obtained:

Engine	A	B	C
Specific consumption (lbs./h.p./hr.)	.545	.454	.358
Total metal weight (lbs.)	2,800	2,000	2,000
Weight per B.H.P.	2.8	2.0	2.0
Lbs. fuel per hr.	545	454	358
Lbs. oil per hr.	35	26	22
Tanks (lbs. per hr.)	20	20	20
Total wt. per hr., supplies	600	500	400
Wt. per B.H.P. for 10 hrs.	8.8	7.0	6.0

Figured on this basis, the plane fitted with engine *B* could fly 4 hours longer than would be possible if engine *A* were installed, and if engine *C* were used, a flight of 9½ hours in excess of that with engine *A* could be maintained. On a mileage basis this would mean about 400 to 760 miles increase in cruising radius, or a 20 to 61.5% gain. If cargo carrying capacity was what was desired, the plane fitted with engine *C* could fly as far as if fitted with engine *A* and carry 3,800 lbs. more of freight or passengers. Economy then, both in metal weight and more particularly in the use of fuel and lubricant, is necessary in an aeroplane engine if it is to compete successfully for use in anything but very short flights.

As is now well known, the maximum efficiency that can be expected for engines operating on the Otto Cycle is expressed mathematically by the equation $E = 1 - \left(\frac{1}{r}\right)^{n-1}$ where: r = the ratio of the total volume of the cylinder to the compression space and $n = 1.408$.

While the above definition for the compression ratio (r) is the one almost universally used, no allowance has been made for the retarded closing of the inlet valve. Aeroplane engines which have inlet valves timed to close 50 or more degrees past bottom center do not actually start compression until these valves are closed so that the true compression ratio is more exactly expressed by the ratio of cylinder volume at the closing of the inlet valve to that of the compression space. The correction factor for the first ratio would be approximately $\frac{1+\cos a}{2}$ where a is the angle of inlet valve retard. And the corrected ratio R would be obtained from $R = r\left(\frac{1+\cos a}{2}\right)$ Thus for an engine whose compression ratio figured on total cylinder volume was 6 and which had a 50° retarded inlet valve, would have a corrected value of 4.92, which partly explains why some of the high ratios used today work satisfactorily when it seems they would fail.

An inspection of the above equation shows that the theoretical efficiency depends solely upon this compression ratio and that the higher this ratio the more efficient the engine.

Fig. 2 is a curve showing the change in efficiency with change in r, and is plotted from points computed from this formula. It is obvious that we cannot hope to exceed the values thus indicated. This efficiency is that developed by the cylinder itself and does not take into account the losses between the cylinder and propeller. As the efficiency we are interested in is the ratio of the work done at the propeller hub to the power available in the fuel, it is necessary to multiply these values by the mechanical efficiency of the engine. Furthermore, we can never hope to get engines whose pistons fit so tightly that there are no leakage losses nor cylinders that do not require cooling. Therefore perfect adiabatic compression and expansion cannot be expected. The maximum value for n is therefore taken at 1.35. Considering these losses, a new curve has been drawn showing efficiencies which it certainly seems impossible to exceed, but which it may reasonably be expected to be approached. At present, aeroplane engines are operating on efficiencies varying from 20 to 30 per cent, averaging about 23, so it would seem that there is some slight room for improvement, although any considerable increase cannot be expected in an engine whose efficiency is now as high as it is; yet it seems inexcusable that aeroplane engines should not operate at efficiencies equal to the best and every effort should be made to improve upon the now best obtainable values.

It has been said above that the theoretical efficiency is improved by an increase in the compression ratio and actual tests confirm this theory. Accordingly, it is to be expected that the proper choice of compression ratio is one of the most important points in design. Unfortunately, however, there is an upper limit to this ratio, a limit imposed by the heat resulting from the compression of the mixture itself. If the temperature of this mixture remained absolutely uniform throughout as the compression increased, it would finally reach a value where the whole would ignite instantaneously and detonation would result. The exact temperature at which this would take place has never been accurately determined, but is not more than 985°F. In the engine itself there is always some part that is hotter than the others, with the result that when these high temperatures are approached one section of the mixture ignites, setting off the rest, so that in estimating the maximum allowable final compression temperature an allowance must be made, depending on how evenly it is believed the cylinder temperature will remain, something nearly impossible to estimate exactly.

As the only limit to compression is the increase in temperature due to its pressure rise and contact with the heated engine parts, it follows that if by some means the charge could be compressed isothermally, the efficiency could be greatly improved. But obviously with high speed engines this is impossible.

If the fuel used by the engine were pure air, the temperature of compression at the inner dead center would be represented by the expression $T_2 = T_1 (r)^{n-1}$ where $n = 1.408$. Actually, however, the charge is a mixture of gas and air, which has a changing specific heat with a change in temperature, and as there is an appreciable

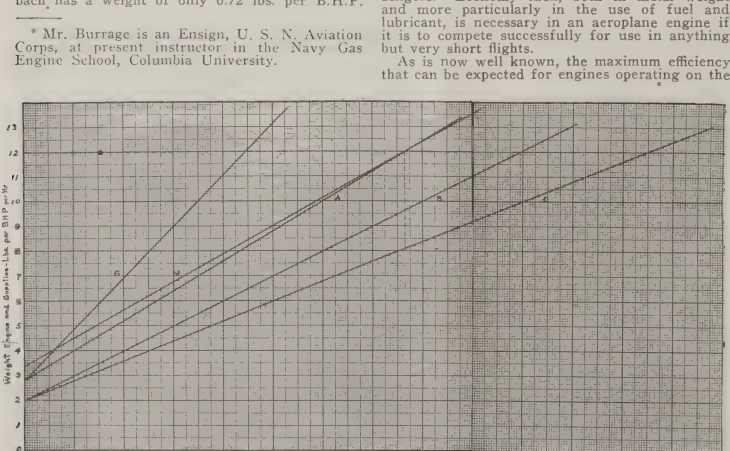


Figure 1.—Graph showing differences in characteristics of representative aeroplane power plants

* Mr. Burrage is an Ensign, U. S. N. Aviation Corps, at present instructor in the Navy Gas Engine School, Columbia University.

time between the beginning and the end of compression there is some loss of heat during compression, so that a value of 1.35 for n expresses more nearly the real compression curve. Using this value, a family of curves have been drawn, showing the final temperatures attained for different compression ratios and for different initial temperatures.

Inasmuch as dry, homogeneous mixtures can hardly be expected with an initial temperature of less than 100° F. with the present day fuels, it is impracticable to consider anything below this value. What is more nearly the real initial temperature is in the neighborhood of 300°F. Keeping this value in mind an inspection of the curves shows that a real compression ratio of from 5 to 6 seems all that could be expected without obtaining self-ignition of the charge. Of course, if by some means, we could obtain initial temperatures at the start of compression in the vicinity of 200 or 250° the ratio could be increased to 7 or 7.5 but at this time it seems unbelievable

As engines are now operating with an apparent ratio of 6.55 the limit seems to have nearly been reached, unless a new fuel is introduced that permits of higher temperatures before self-ignition. Furthermore, as these highest ratios are approached, the gain in efficiency is not as great. There are several reasons for this, all of which depend on the increased heat, generated as a result of the high compression. First of all high compression pressures cause high explosion pressures and therefore higher temperatures throughout the cycle, which raise the mean temperature of the walls, valves, piston, etc., and these increase the temperature of the next charge resulting in its ignition before the piston reaches top center. With this condition, mean effective pressures are not proportionately as great and the gain in thermal efficiency becomes less.

The increased heat of the exhaust gases also tends to increase the initial compression temperature as the gases left in the clearance space intermingle with those of the incoming charge. In addition, the heat loss to the cylinder walls is greater with higher temperatures which partially offsets the gain due to the higher compression. In other words the inability to control the heat of both the gases and metal parts of the cylinder form a limit to the compression ratio.

The reasons for the increase in efficiency with a high compression ratio are (1) reduced area of wall surface exposed to the combustion, (2) reduced time of explosion, (3) reduced amount of dilution of incoming charge. Opposed to this is the increased heat loss caused by the greater density of the charge and greater temperatures. Obviously the greater the amount of compression the smaller the amount of cylinder wall and head area of cylinder exposed to the explosion. This means that for a given weight of charge the resulting temperature of explosion will be greater as there is less cooling surface to cause heat removal and of course the pressure will be correspondingly greater, and more power obtained from the engine for a given heat supply. It is well known that high compression pressures cause an explosion that is not only more powerful but also more rapid, and since less time is consumed

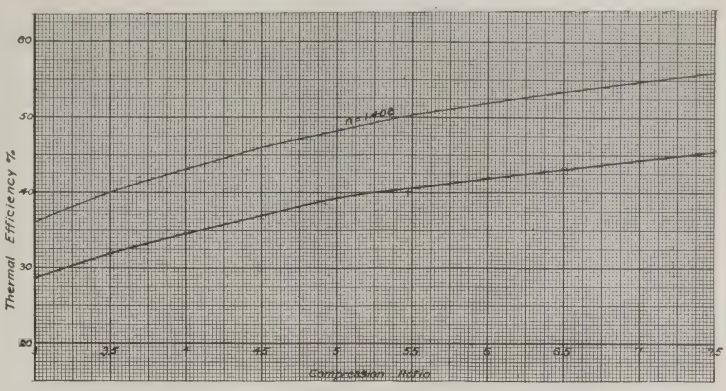

Figure 2.—Curve showing change in efficiency

in the attainment of maximum pressure there is less time in which heat can escape and thus it is more efficiently utilized. In engines with a small clearance space there must of necessity be less burnt gases left in the clearance to intermingle with the fresh charge, detracting from its power and raising its temperature. But as the density of the mixture is increased by compression, the temperature is also increased during this period and a slightly greater loss of heat to the walls results. However, as this increase is only a little over 100°F for an increase in compression ratio of from 4.5 to 6.5 the loss is not great. The overall result is therefore a gain in efficiency.

Next to the compression ratio the most important effect on efficiency is the form of the combustion chamber. Practically no one builds aero engines to day with *L* or *T* heads although there are quite a few modifications of cylinder head shape using overhead valves. Undoubtedly the best form of combustion chamber from the standpoint of high thermal efficiency is that of a sphere as the surface exposed to the explosion is the least possible for a given volume, and the least loss from cooling results. This has been proven by the actual designs over and over again although it is doubtful if the added trouble taken to make the piston head concave has been worth while in added efficiency. So long as the general shape is spherical the increase in volume-surface ratio gained by making it absolutely so must be slight, and as any constructional difficulties present themselves a change would probably not be worth while.

Not only does the form of the combustion chamber affect the efficiency but also the finish of the interior walls. It is well known that a rough or irregular surface radiates or absorbs heat more readily than a smooth one and if the walls of the combustion chamber are highly polished the heat radiated from the charge will not be as readily absorbed by the chamber walls, resulting in higher temperatures with a correspondingly higher thermal efficiency. Thus it is seen that with aero engines it undoubtedly pays to machine the interior of the combustion chamber.

The dimensions of the cylinder as well, have their effect on the fuel economy. As a combustion chamber whose wall area is the minimum possible for the volume it surrounds gives the least heat loss, any change in cylinder dimensions that would tend to decrease the ratio of surface to volume would be productive of good results. Now since the volume of a solid varies as the cube of the linear dimensions and the area as the square, the larger the cylinder diameter the less the percentage heat loss and the more efficient the engine, other things remaining equal. But there is a limit to the gain thus effected, a limit imposed by the quantity of heat that can be taken care of in the cooling of the cylinder in order to keep the operating temperatures so low that the metal does not burn or distort, nor too great suction heating result. With the present rate of heat generation this limit is reached with cylinders 5 to 5½ inches in diameter. This effect of cylinder diameter on efficiency is well substantiated by actual engines the larger of which are, on the average, more efficient.

But when an increase of stroke is considered as well as diameter the problem readily becomes one of a comparison of long vs. short strokes. Here the gain or loss is by no means so clearly defined as there are several compensating factors to be considered.

For two engines having the same piston displacement and the same compression ratio, the one with the longer stroke has the smaller ratio of interior cylinder surface to volume when the piston is at the inner dead center. It may, therefor, be inferred that from this consideration alone the longer stroke engine is more efficient. But on the other hand, the long stroke engine takes a longer time for expansion, provided it is operated at the same piston speed, so that the expanding gases remain longer in contact with the cylinder walls and consequently lose a greater percentage of their heat to these walls. These conflicting tendencies have different values at different engine speeds. At low engine speeds it is probable that in the case of the long stroke engine more is lost during the period of expansion than is gained during the explosion period and hence the short stroke design is the more efficient. But as the engine speed is increased the loss during expansion becomes smaller and the long stroke engine becomes more efficient. In aeroplane engines, however, excessively long strokes are barred by reason of the resulting increase in weight, and hence much gain cannot be expected from this source.

As has been suggested above, speed of revolution has a pronounced effect on economy. A consideration of extremes of operation shows this. If the engine is running *very* slowly, the induced charge will have more time to become warmed to the engine temperature and the weight thus drawn in will be reduced. Also, the time consumed during the explosion will be comparatively large and the heat leakage thereby increased. In addition, the loss during expansion is greater resulting in poor economy and the maximum compression ratio that could be used would be lowered. The higher the speed then, the less chance for heat loss. But there is a limit to this, and while the efficiency improves with speed, as the engine approaches the maximum values the improvement becomes less pronounced and finally falls off as extreme speed is reached. This is to be expected, for at the highest speeds the limiting temperatures have

(*Continued on page* 1170)

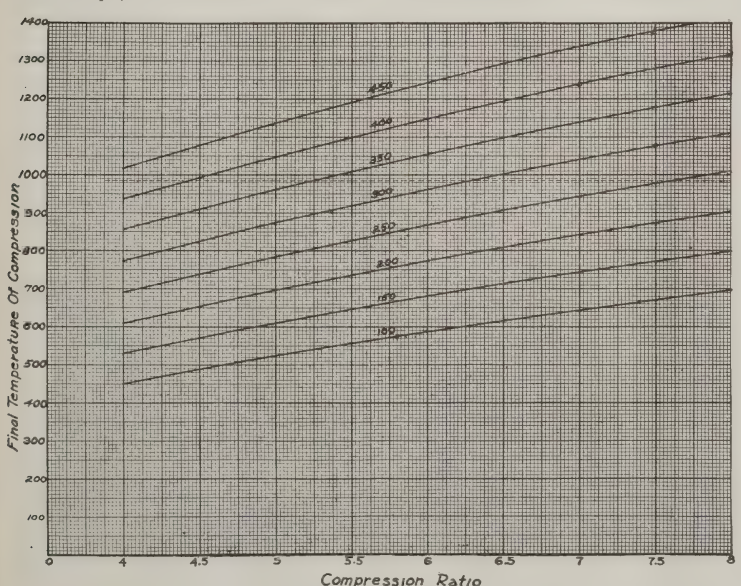

Figure 3.

ADMIRAL MAYO'S AIRSHIP REPORT

A REPORT made by Admiral Henry T. Mayo, U.S.N., to the Secretary of the Navy on the development of the rigid and non-rigid airships and plans for their future development in the British navy was presented to the House of Representatives by Secretary Daniels on February 6 in response to a request from the House Committee on Naval Affairs for information as to why the Navy Department wanted $25,000,000 for aviation purposes. Mr. Daniels explained that "a larger appropriation for lighter-than-air aircraft is requested because in this respect Navy aviation is not as far developed as in the heavier-than-air aircraft."

Admiral Mayo begins his report, which is dated November 3, 1918, with the statement that "the failure of the Zeppelins in the raids over Great Britain and the destruction of several Zeppelins over the North Sea by planes carried on cruisers, and on one occasion by a large American flying boat, has induced the belief in the minds of many officers that the lighter-than-air ship has been definitely displaced by the heavier-than-air machines." He then points out that officers who have had most to do with the lighter-than-air type contend that the types of Zeppelins used in the air raids were unsuitable for the purpose and continues: "The improvement in the lighter-than-air ship design have been such that the latest German rigid airship has a speed of about seventy to eighty miles per hour, a ceiling of 24,000 feet, and a rate of climb superior to any plane. With these characteristics a rigid is comparatively safe against attack from anti-aircraft guns or heavier-than-air machines. Additional safety has been assured to the lighter-than-air ship by the development of a non-inflammable gas (helium) of which the United States possesses almost limitless natural resources."

The airship's chief value in naval warfare, Admiral Mayo states, is in scouting and in keeping large areas of the sea under observation. He considers the rigid type of airship essential to the highest efficiency in the above two classes of utility and states that the latest type of these ships developed by the British (R-38 class) has 2,720,000 cubic feet capacity and an estimated cruising endurance at forty-five miles per hour of 11 hours, thirty-four hours greater than the German L-70 class, which was produced in 1918. Admiral Mayo gives a slight sketch of the progress made in the British navy up to 1915 with the lighter-than-air ships and states that "it appears regular voyages of startling length are planned for these craft." He adds: "In times of war these airships can be concentrated over any area of the seas surrounding English possessions to hamper hostile surface craft and to assist the navy in its operations."

Germany's Airship Program

The report continues: "The results already attained have justified the confidence felt by the German navy in its airships when used in their proper sphere as the eyes of the fleet. Their Zeppelins did much to save the High Seas Fleet at the battle of Jutland, to save their cruiser squadron on the Yarmouth raid, and were instrumental in sinking the Nottingham and Falmouth. Had the position been reversed in the Jutland battle and had the British had rigids to enable them to locate it, they would probably have annihilated the German High Seas Fleet. At the present time Germany possesses apparently fifty efficient rigid airships built since 1915, in addition to a few non-rigids which she uses only for training purposes. The Schutte-Lenz works, which build rigid airships, take about two weeks to build each ship. The maximum output of their factories is one ship every sixteen days. Germany's total output of rigid airships would therefore appear to be thirty rigids a year, or one every twelve days. The latest information shows that Germany has fifty-four housing and constructional sheds, capable of holding seventy-one rigid airships. This surplus of shed accommodation, placed all over the country, enables ships which cannot get to their base after a long cruise to make for vacant berths where the weather conditions are more favorable.

British Rigid Airships

"While no other nation has done as well as the Germans in rigid airships, the British, alive to the need of maintaining sea supremacy, are closely competing. A few days ago they held acceptance trials of a 1,400,000 cubic foot ship (the R-31), which made over fifty-five knots and could lift eighteen tons (or, say, 200 persons). This ship turned in a complete circle of 0.7 mile diameter in three minutes. Another British ship now under way (R-38) will have a displacement of 2,750,000 cubic feet, a speed of about seventy knots, and a range of well over 200 hours, or safely across the Atlantic and return in any weather except the worst storms. The British, who, despite having shot down so many bombing Zeppelins, are keenly aware of their utility, are embarked upon a construction program of sixteen of modern type (besides smaller, now obsolete, types already in commission and used for training); the French, have a similar program, calling for eight; it is understood the Italians are to construct two and our joint Army and Navy rigid airship board has recommended that we begin with four for the Navy.

The development of the non-rigid airship is practically at a standstill, while the development of the rigid type is being pushed by Germany, France and Great Britain. The future of the rigid airship depends upon the ability of its designers to secure for it a superiority, relative to heavier-than-air craft, in radius, ceiling, climbing ability and an approximation to the speed of the fighting planes."

High Thermal Efficiency in Engine Design

(*Continued from page* 1169)

been reached, with tendencies toward preignition and less efficient combustion.

It has been claimed by some that an offset cylinder is productive of higher efficiencies. The reason given is, that as the piston travels more slowly on the induction stroke the amount of charge is greater in density and cooler. But as the engine is certainly warmer than the charge, any additional time would seem to be a detriment to coolness which is essential to maximum weight. Then too, as the piston is supposed to remain longer at the top of the stroke, thus giving more nearly the conditions of constant volume, the pressure is supposed to be greater. But when the actual differences in time and strokes are figured out for the ordinary amounts of offset given it is found that they are so small in magnitude that any pronounced difference in economy is unbelievable, especially as the result of the changes produced are contradictory to each other. But with the proper amount of offset the mechanical efficiency is improved owing to the reduction in piston friction and a slight gain in power output is effected. Now as the thermal efficiency under discussion is based on the brake and not the indicated horsepower, the result of offsetting is a slight improvement in economy.

Probably the most important of the conditions for efficiency is that of the proper quality of the mixture fed to the engine. Everyone knows that excessively rich or lean mixtures can not give the best results, but the exact proportions are more or less in doubt. A mixture that is only slightly rich has often been observed to give maximum power and because of this it has sometimes been thought that the best power for the heat supplied had been obtained. By definition a rich mixture means that there is an excess of fuel to the amount of air and consequently, as there is not enough oxygen to burn all of the gasoline, some passes out unburnt. Of course, no work at all is obtained from this and there is obviously waste.

With a lean mixture, however, there is an excess of air, which means that this extra oxygen and its accompanying inert nitrogen must also be heated up and pass out the exhaust. A lean mixture is slow burning as well, so that the power output is reduced and the efficiency lowered. But in the case of mixtures that are only slightly lean the excess air serves to reduce cylinder temperatures, permiting of a higher compression without self-ignition and lowering the final temperatures of explosion so that the temperature difference between the charge and the wall is lessened and the radiation loss cut down somewhat. Of course the power obtained is not as great, but the percentage of power obtainable from a given amount of fuel is increased. This mixture ratio for optimum efficiency is about 17 to 1, varying with the fuel used and the compression ratio. As might be expected, the mixture for optimum efficiency, in the case of high compression engines, is slightly leaner the higher the compression, as these extremely high temperatures are more favorably affected by the cooling effect of the excess air.

As the most rapid explosion possible is desirable in order to reduce the time for heat to radiate, the location of the spark plug has some bearing on the economy of engine operation. Two sparking points are better than one, as has been proved over and over again, but there is still some controversy over the exact location in the cylinder in which to place them. It would seem natural that to locate them in such a way that the distance from either plug to the most remote part of the mixture was a minimum would result in the quickest explosion, the greatest power and best economy. Tests, however, have failed to show any appreciable difference in engine operation of one method over another and accordingly they have been located wherever is most convenient for the designer. Needless to say, the electrical system must be so timed that the sparks from the two plugs occur simultaneously to obtain any advantage.

The time that the spark occurs in relation to the piston position is another contributing factor to economical operation. To obtain the highest possible pressure from a given charge the inflammation part of ignition should be completed before the piston has moved an appreciable distance out on the down stroke. Furthermore, the charge should not be ignited so soon that inflammation will be completed before the piston has reached the top of the stroke. In other words, the point where this process should be completed is a very definite one, and to alter it the least bit is to reduce the power obtainable. As the engine may revolve at various speeds and as the time occupied by inflammation for ordinary engine conditions is approximately constant, it is seen that ignition must be started at earlier points on the stroke at higher speeds in order to have it end at the proper point. Hence, there is only one point for the spark advance at any one speed, if it is desirable to obtain the best that the engine can do. The great advance necessary at the highest engine speeds forms one of the limits to efficient operation at these speeds and so anything that will reduce the time of inflammation will improve economy.

With an increase in altitude compression pressures fall off and accordingly the engine can stand a greater spark advance at constant engine speed, for, owing to the reduced pressure, the time of the explosion will be less.

Another operating feature affecting economy is the kind of fuel carried. Although high test gasoline is far more expensive, a plane can fly further with a fixed *weight* of this fuel than with the same weight of low Baumé gasoline. While, on the other hand, for a fixed *volume* a longer flight may be made with the low test fuel. And, if prophesies are fulfilled, the new fuel developed during the war has a promise of better economy than any of the gasolines.

Although a high engine speed is desirable from the standpoint of economy, it should be driven at a speed that gives the plane the most mileage for a gallon of fuel, and this is not its maximum speed. In fact, the relations between engine and propeller speed and that of the plane itself must be definitely understood if the pilot is to get the best mileage from his machine.

The proper altitude at which to fly the machine is governed by so many variables that definite laws are hard to formulate. Should the machine encounter at a certain altitude strong steady winds blowing in the desired direction of flight, there is no question but that more miles per gallon could be accomplished with its aid. In general, however, better economies can be made at the lower altitudes, although it has been shown that for the same power developed the economy is the same at a higher altitude but at a higher engine speed. Minimum consumption, however, never attains as low a value at the higher altitude.

Engines using high compression ratios may exhaust as much as 40% of the heat of the fuel, for high speed engines have not the same time to allow the waste heat to get to the cooling water. One of the reasons given above for increased efficiency of high speed was the reduction of the time during explosion and expansion and the consequent reduction of the amount of heat lost to the jackets. But at the same time, all of the heat thus saved is not used in useful work, and hence the higher the speed the greater percentage of the heat passes out the exhaust. The following might be a possible heat balance of a high speed engine: useful work, 30%; exhaust, 40%; lost to water jacket, radiation, etc., 30%.

Now, in some of the latest planes, engines totaling as much as 2,400 B.H.P. have been constructed. This means that fuel having a total heating value equal to 8,000 H.P. is used in developing the useful 2,400 H.P., and that 3,200 H.P. or its equivalent in B.t.u.'s passes out the exhaust. With units as large as this the heat thus wasted is enormous, and it is not inconceivable that some successful device will be perfected that can utilize some of this heat. It may be that only 5% or 10% could be reclaimed, but even then it would amount to 160 or 320 H.P., a quantity that would drive a plane of small capacity. And so with the larger power plants greater economies may be possible.

It is not expected that any or all combinations of the features mentioned will yield the best economy. Each design of engine has, for example, an optimum compression ratio beyond which it would not be of advantage to go to give the best results. And so each part of the design must harmonize with the others; combinations intelligently made and carefully tested, until the best possible or best feasible design is attained.

AEROPLANE AND SEAPLANE ENGINEERING

By Commander H. C. RICHARDSON, U. S. N.

THE problem confronting the Navy was largely determined at the time the United States entered the war by the fact that the operations of the German and Austrian fleets had been reduced principally to minor raids from the fleet bases at Kiel and Pola, and the only real seagoing operations comprising the activity of submarines.

The work of the seaplanes, therefore, was primarily reduced to that of cooperation with the fleet in reducing the submarine menace. This naturally led to the establishment of coastal stations in France, Italy, England, Scotland and Ireland. In these operations it was possible to operate seaplanes from shore bases in practically every case, and the development of work with the fleet became a minor consideration.

Some of the seaplane bases, however, were sufficiently close to enemy territory to be within raiding distance of enemy planes of both land and water types, and it became necessary for the Navy to extend its activities to the use of land planes for the protection of seaplane bases, and naval aviators also participated in big bombing raids on German and Austrian territory.

I refer to these matters in this general way, not to describe these activities, but to show that in naval work both land and water planes were used, and why the Navy problem was in general restricted to operation from shore bases rather than operation from ships. Activities, however, were not confied to shore bases in Europe. Stations were established on the Atlantic coast, principally for the purpose of submarine patrol and for convoy work from the principal ports from which our troops and supplies were sent abroad.

Paper presented at the Annual Meeting of the Society of Automotive Engineers.

Types of Planes Developed

The work of seaplanes abroad was that of submarine patrol and convoy work, and this having been determined on, all efforts were made to obtain the most suitable seaplanes for the service. The principal work was done with two types of seaplanes, namely, the HS-2—the single-motored plane developed from the HS-1—and the H-16, a copy of the English seaplane of the same type developed as a result of Commander Porte's experience with the original America and subsequent types developed therefrom. Finally, the F-5L type was developed from English designs for manufacture in this country by the Naval Aircraft Factory at Philadelphia. The HS-2 and the H-16 have proved well suited to the work required, but the F-5-L did not enter production early enough to get into active service before the armistice was declared.

The Navy did not attempt to develop land plane types, but accepted and used those which had been developed and produced for the Army, adopting for this purpose the English Handley-Page, the Italian Caproni, and the Army DH-4 and DH-9.

In order that pilots should be trained for this service, it was necessary to adopt training planes, and for this purpose the Navy developed and used the Curtiss N-9, the R-6 and the R-9, the Aeromarine and Boeing seaplanes, and the F-boat; and also experimented with a number of miscellaneous types, such as the gnome scouts—both biplane and triplane of Curtiss and Thomas manufacture—and the Gallaudet D-5. The most successful of these training planes was the N-9, particularly after the original float had been modified and later on after the substitution of the Hispano 130-h.p. engine for the OXX 100-h.p. engine. This plane was a biplane tractor with a single center float, having wing tip balancing floats. It was remarkably strong and could perform practically all sorts of maneuvers. Although in training work it was frequently wrecked, there were remarkably few deaths resulting. This I attribute to its moderate speed, remarkable strength of construction, and tractor arrangement, which made it emininetly suited for training purposes.

As soon as it was determined that seaplanes of the flying-boat type were to be used in service it became necessary to provide preliminary training in a type of seaplane which more nearly represented the conditions of operation of the big boats. For this purpose the F-boat originally developed by Curtiss for sporting and for naval use was modified and adapted to instruction purposes.

I shall later on describe and illustrate the principal types referred to.

So far as the aerodynamical and mechanical features of construction are concerned, seaplanes differ very little from aeroplanes, the principal difference being the use of the landing gear suited to operation from the surface of the water instead of from the land. The proportions are, naturally, somewhat different, and the performance is different; primarily, because of the greater inertia due to the greater weight involved in the seaplane construction than is the case in the seaplanes. But bearing

Commander Richardson inspecting the N.C.1

this in mind, the details of construction of seaplanes are substantially the same as those used in aeroplanes.

Factors Affecting Performance

It will now be of interest to consider the principal factors which affect performance, as it is necessary to understand these completely to develop a design which shall perform according to the requirements of the service intended. For the purpose of illustrating the factors involved I have prepared a set of performance curves, which I believe will give a clear insight into this phase of the problem. The complete calculation of the curves shown is given in the Appendix, together with the formulas involved in the computations.

The performance in power flight is determined by the horsepower required and the horsepower available, and, of course, the latter must always exceed the former or power flight is not attainable.

In determining the power required there are two principal factors involved. The first factor is that of the horsepower required to propel the planes with their load in flight. This horsepower I term the plane's E.H.P. To determine it, is is necessary to know the form and disposition of the wing surfaces used, as well as the aerodynamic characteristics of the wing section employed. The lifting power of the wing depends on the area and the square of the speed of advance, and its resistance is also in proportion to the area and the square of the speed of advance, the speed of advance being the speed relative to the air itself and not to the speed over the ground.

The lift of an aeroplane surface and its resistance to advance are determined by the lift and drift factors, which vary with the type of section used and also with the angle of attack at which the surface is presented to the relative stream of air. It has been found by experiment that these factors are influenced by the proportion and arrangement of the surfaces, the best results being attained with what is known as the monoplane surface.

Performance is improved by increasing the dimension of the wings in the lateral sense, over that of the fore-and-aft dimension. The ratio of these two dimensions is called the aspect ratio. As the aspect ratio is increased, it is found that the efficiency is improved indefinitely. But after an aspect ratio of 8 or 10 is attained the improvement in efficiency becomes less and less, and, practically, is not worth going after, because the dimensions become unwieldy and the gain in lifting power and efficiency may be more than wiped out, due to the increased weight and resistance of the structure required in employing same. It is largely on account of this difficulty that the biplane and the triplane have been used where large lifting power is required, even though in the latter cases the efficiency of the surfaces is reduced because of interference of the air flow, which is found to depend upon the gap ratio. By this is meant the ratio of the distance between superposed planes to the chord length, or fore-and-aft dimensions of the wings.

Where the leading edge of the upper plane is forward of the leading edge of the lower plane the efficiency is improved over that where one plane is immediately above the other, and conversely. This arrangement is referred to as stagger and the condition of positive stagger, that is, with the upper wing forward of the lower wing, is generally adopted with the view of improving efficiency. There are limits to its usefulness because of the obliquity of the trussing involved.

Stagger may be adopted for various reasons; such as correcting the balance of an aeroplane in which the actual location of the center of gravity does not conform to that originally contemplated, or, in order to improve the view of the pilot or observer, particularly if the latter is also a gunner.

The efficiency is improved if the upper plane has a greater lateral dimension than the lower plane. This disposition is known as overhang. There are limits to the extent to which this can be employed, on account of the structural difficulties involved.

In the normal type of construction, the front and rear edges of the wings are parallel, although it is found that tapering the wings to a smaller fore-and-aft dimension at the wing tip improves efficiency. This arrangement is not satisfactory from a manufacturing point of view, as it involves different sized ribs at every station in the wings. All the above considerations power—the movement of the center of pressure is such as to cause instability longitudinally. faces. It is found that where wings have a cambered surface—which is usual in aeroplane construction because of the superior lifting have to be taken into account in determining the form and proportion of the wing surfaces.

Another factor is very important, that is the travel of the center of pressure on the wing surfaces. It is found that where wings have a cambered surface—which is usual in aeroplane construction because of the superior lifting power—the movement of the center of pressure is such as to cause instability longitudinally. Various devices have to be employed to overcome this. The most satisfactory and usual method is to employ an auxiliary surface at the tail of the aeroplane called the horizontal stabilizer, and the best conditions for stability are found when this rear surface has a smaller angle of attack than the wing surfaces themselves.

This difference of angle between the wings and the horizontal stabilizer is termed "Longitudinal dihedral." The stiffness or steadiness of an aeroplane in flight depends on the area, proportion, section and angle of the rear surface. Where great stiffness is desired, this rear surface may even assume the proportions of a second set of lifting surfaces which may be of monoplane or biplane arrangement, usually of smaller dimensions than the main planes. Where the rear surfaces are increased to near the proportions of the forward surfaces, the tandem biplane arrangement is approached.

For military purposes and for combating rough air conditions it is found desirable to have initial longitudinal stability, but it is undesirable to have this in a high degree on a military plane in which steadiness may be essential to the proper operation of a gun or a bumb-dropping device. If the rear surface were completely fixed relative to the forward surface it would only be possible to proceed in horizontal flight at one definite speed for the load carried, and ascending or descending could only be accomplished by increasing or decreasing the power, or by decreasing or increasing the load. These methods of control are not sufficiently accurate or active, and it is much more satisfactory to use additional surfaces, known as elevators, appended to the rear margin of the horizontal stabilizer, which by modifying the action of the stabilizer make it possible to proceed in horizontal flight at any speed from the minimum to the maximum flying speed, or to cause the plane to rise or descend. In some aeroplanes, in order to get the maximum of maneuvering ability, the horizontal stabilizer is reduced to a very small area, or, even, in some cases, is completely dispensed with, all being merged into the elevator.

In the original Wright machine lateral balance was maintained by warping the wings, but this method is unfavorable to strength in large structures, and the use of ailerons for this purpose has now become general.

In flight, aeroplanes are not always operated so that the trajectory conforms to the axis of the aeroplane, particularly when turning or when encountering side gusts, etc. As a consequence, unless what is known as the keel surface of the aeroplane is distributed equally above and below the center of gravity, there is a tendency for the aeroplane to roll one way or the other, depending upon the location of the center of gravity relative to the center of lateral pressure. To compensate for this effect, or to provide lateral stiffness under such conditions, it is usual to provide a moderate amount of what is known as lateral dihedral; that is, the wing tips are higher than the center portion of the wings; or else skid fins are placed immediately under or above the upper wings. These in general have the same effect as lateral dihedral. By modifying this arrangement the amount of lateral stability can be controlled to any desired degree. Again for military purposes it is desirable to have initial lateral stability, but not to such a degree as to interfere with controlability of lateral balance.

Directional stability is also affected by the location of the center of side pressure, depending upon its location fore-and-aft of the center of gravity. It is essential for steady flight that the center of lateral pressure at small angles of skew should not pass forward of the center of gravity. To accomplish this it is usually necessary to install a vertical stabilizer at the tail of the aeroplane. It is again desirable to have initial directional stability. And again, in a military plane, it is undesirable to have this to such a degree as to interfere with control of direction. As the aeroplane is symmetrical relative to the vertical fore-and-aft plane, it is unnecessary to provide any equivalent of the dihedral effect, and it is only necessary to append a rudder to the vertical stabilizer in order to control direction. In some planes, where extreme maneuverability is desired, the rudder itself, in its neutral position, performs the functions of a vertical stabilizer as well as that of a rudder, and no vertical fixed surface is used.

Location of Power Plant and Crew

Having given due consideration to the influence of the proportion, arrangement and disposition of the main supporting and control surfaces, it is next necessary to consider the service intended and the location of the power-plant and the crew. The possible arrangements are almost infinite, but in general it is desirable to locate the pilot centrally where he will have a proper view to enable him to handle the aeroplane to the greatest advantage and this is particularly necessary to the combat plane. It is also essential that the gunner shall have as large and unobstructed view as practicable, and that with the gun positions selected he shall be able to cover with his arc of fire as much of the surrounding sphere as is practicable, in order that there shall be no dead spots from which the enemy may approach without his being able to return the fire. This sometimes requires that the pilot himself shall be able to operate guns, firing dead ahead, or that additional gunners shall be placed so that they can cover arcs of fire not possible for the others to cover.

In bombing planes, and in particular in night bombing planes, this requirement is of less importance, and the requirement that the bomb dropper shall have a proper view for the operation of the bomb sights becomes of prime importance.

For aeroplanes designed for long-distance flights or for bombing, it becomes necessary to have great power available and this requirement has led to the adoption of multiple unit powerplants. Two, three, and as many as five powerplants have been successfully used for this purpose. The multiple-engine plane has the advantage that in case of damage to one powerplant it is usually possible to continue flight with the remaining power plants; or, if still too heavily loaded to accomplish this, it is possible to stretch out a glide for a long distance and thereby make it possible to select a more favorable landing place and often to avoid landing in enemy territory.

All these and many other considerations enter into the disposition and arrangement of the powerplant and fuselages, and these arrangements themselves have an influence on the performance of the wing surfaces because of interferences involved.

By winging out the powerplants a more favorable load distribution is imposed on the aeroplane structure and advantage is taken of this feature in designing the wing trussing. The effects of interferences and of the disposition and proportion of the wings or bodies and auxiliary surfaces are so complex that unless data are already available from similar designs, it is very desirable that the resistance and lifting power of the complete design should be determined from wind-tunnel tests of a model carefully constructed to scale in every detail. Such model test is usually deferred until the design has approached some definite form after preliminary estimates have shown that it is capable of approaching the performance desired.

Form and Proportion of Wings

In preliminary estimates the influence of the form and proportion of the wings is carefully estimated, and from these estimates a fairly accurate approximation of the horsepower required for the planes is derived. To arrive at the total horsepower required, it is next necessary to consider the horsepower required to overcome the head resistance. In order to do so, it is necessary to have accurate knowledge of the resistance of all elements of the aeroplane structure exclusive of the wings, which are exposed to the action of the wind in flight.

To reduce the resistance of these elements to a minimum, streamline forms are adopted wherever practicable, and even the truss wiring is made up of streamline form; or, if this is not found practicable these wires are covered with false streamline covers of wood or metal. It is found that the reduction in resistance more than compensates for the additional weight involved in applying these false covers.

The resistance of the fuselages, radiators, engines, tail control surfaces, and elevator rudder and aileron horns and all other elements is computed in detail, and account is also taken of the obliquity of these elements to the flow of the air. Such obliquity is found to exert an important influence on their action. For preliminary estimates, it is customary to determine the resistance of these elements for the position assumed by them at some speed intermediate to the low flying speed and to the high speed attainable with full power, and then to assume that the resistance of these elements is proportional to the square of the speed for speeds above and below and intermediate speeds selected. This is most handily done by assuming that the resistance of these elements is represented by a flat surface exposed normal to the wind, which would have the same resistance as the aggregate of these elements. This supposititious surface is what is referred to when we speak of the "surface of equivalent head resistance." In the example which I have chosen to illustrate, "the equivalent head resistance" is assumed to be 20 sq. ft., and the horsepower required to drive this head resistance through the air is indicated on the curve denoted head resistance horsepower. By compounding the ordinates of this curve with the ordinates of the plane's EHp. curve we derive the total EHp, required curve.

We have next to determine the total brake horsepower available in order to determine the performance of the aeroplane. To determine this curve, we must first know the full-throttle characteristic of the engines to be used. This characteristic is indicated in the example showing the brake horsepower available at different speeds.

The next thing to be determined, and the one having a most important influence on the performance of the aeroplane, is the propeller characteristic. To date the progress in propeller design has been far from satisfactory, and although good results have been obtained, the best results possible have seldom been approached. In the selection of the propeller, one of the first considerations is to determine what feature of performance is most important, for it is necessary to select the proper dimensions with a view to gaining the best results for the service intended. For instance, if high speed is of greatest importance, the propeller to be selected will differ materially from that which would be re-

quired if great climbing power is desired, because the greatest climbing power will be attained at a much lower speed than the maximum speed. Or, it may be a question of selecting a propeller which will give the greatest efficiency at cruising speed, and this propeller will usually differ from that selected for either of the preceding cases. In some cases it may be desirable to select a propeller which will give the best all-around performance rather than for a particular condition.

In seaplane work a problem arises which is not found in the land aeroplanes. This problem is that of obtaining the greatest reserve of power to overcome the resistance of the float system, because it is desirable to have the greatest possible reserve to accelerate rapidly on the water so that the getaway may be made in rough water with the greatest possible rapidity, thereby reducing the punishment which the seaplane suffers under such conditions. For a heavily loaded seaplane this consideration may be of vital importance.

Efficiency of the Propeller

It must be understood that the efficiency of an aeroplane propeller is absolutely dependent upon its speed of advance through the air, as is also the power which the propeller absorbs in flight, the result being that even though the full throttle is used the engine cannot make its full revolutions until a good flying speed is attained, with the consequence that full power of the motor cannot be realized until flying speed is attained.

The efficiency of a propeller is dependent upon a function of the velocity and of the number of revolutions and of the diameter of the propeller represented by the *function* $\frac{V}{ND}$. The efficiency, the torque and the thrust, the horsepower absorbed and the horsepower delivered are functions of this quantity, in which velocity the number of revolutions and the diameter must be expressed in the same units.

The influence of this factor is indicated on the propeller efficiency curve based on the values of the fraction $\frac{V}{ND}$. When this fraction equals 0.2 the efficiency of the propeller indicated in the example is only 37.5 per cent. The maximum efficiency is attained when the value of this fraction is 0.59, the maximum efficiency indicated in this case being 73.2 per cent.

In the example chosen I have used a Durand propeller No. 8, whose characteristics have been determined by wind-tunnel tests, as reported in report No. 14 of the proceedings of the National Advisory Committee for Aeronautics—1914.

To derive the dimensions for this propeller I have assumed that it is desired to attain the best results at 80 miles per hour with a Liberty engine operating at 1600 r.p.m. and developing 380 b.hp., as shown by the motor characteristic. In Professor Durand's report he has adopted Eiffle's logarithmatic chart, and I shall now indicate how the diameter of the propeller is determined.

At a speed of 80 miles per hour on the chart (Plate 1) erect an ordinate equal to 380 hp. taken from the scale on the left side of the chart. From the top of this ordinate next draw on oblique line parallel to the line indicating the speed and draw this line of such a length and in such a direction as to represent 1600 r.p.m. on the scale starting with the origin at 1200 r.p.m. From the extremity of this line next draw a line parallel to the line giving the diameter scale, and taking the distance from this point to its intersection with the propeller characteristic for the propeller No. 8 we find that this line intersects at the point O. Transferring the length of this line to the diameter scale and measuring in the direction in which it is necessary to draw this line to make it intersect with the propeller's caracteristic, we find that the proper diameter to use is 9.4 ft., indicating an efficiency of 69 per cent. By the use of this ingenious chart it is possible to select a proper diameter for a given set of conditions by a simple graphical solution.

The diameter now being determined it is next necessary to determine the performance of the combined engine and propeller, and this is done as follows: On a transparent sheet of paper, or tracing cloth (Plate 2), a base line is drawn and, from any convenient point on this line, another is now drawn parallel to the scale of propeller diameters and a distance is laid off representing the diameter of the propeller on that scale. From the extremity of this line a new line is drawn parallel to the scale of revolutions per minute, and on this line is indicated the revolutions per minute of the powerplant, using the scale of r.p.m. for this purpose. From each point representing the different revolutions vertical ordinates are now drawn, representing, according to the horsepower scale, the brake horsepower developed by the engine at these revolutions, and through the points so determined a motor b.hp. curve is drawn.

Next place this diagram on top of the logarithmatic diagram of the propeller, placing the origin on the base line *A* on the base line of the logarithmatic diagram with the point *A* at the speed at which it is desired to determine the brake horsepower available. The propeller efficiency, and from the latter the E.Hp. available, can now be determined.

This construction is based on the fact that the horsepower absorbed by the propeller and the horsepower delivered by the engine must agree. Thus, for example, placing the point *A* at a speed of 30 miles per hour it is found that the brake horsepower curve of the diagram intersects the propeller characteristic and the engine characteristic at a point *B*, indicating that the engine will make 1500 r.p.m. and develop 355 b.hp. at this speed of advance.

By drawing a vertical line through this point of intersection of the two curves to the dotted characteristic of the same propeller, the E.Hp. developed by the propeller may be determined. This can also be determined by measuring the distance on the vertical line between the full line and dotted line representing the propeller characteristics. By transferring the length of this line to the scale for efficiency, the propeller efficiency can be determined.

In this manner the brake horsepower available and the E.Hp. available have been determined and are shown on curves in the example "*B*." It will be seen that at 30 miles per hour the engine can only turn the propeller at 1500 r.p.m., developing 355 b.hp. Also, that at this speed the efficiency is only 35 per cent and only 124 E.Hp. is available, although the engine is developing 355 b.hp.

Determining Plane Performance

Having now determined the E.Hp. available, we are ready to determine the performance of the aeroplane. It will be noted that the lowest speed indicated in power flight is 58.5 miles per hour.

The climbing power of the aeroplane with full power is determined by taking the difference of E.Hp. required and E.Hp. available at the particular speed at which the aeroplane is flown in the climb. This difference is greatest at the speed of 73 miles per hour. The climb is determined from the reserve E.Hp. available, which in this case is 76. Multiplying this E.Hp. by 33,000 and dividing by the weight of the aeroplane, assumed in the example to be 6500 lb., it is found that the initial climb should be 386 ft. per minute.

Further inspection of the curves shows that the minimum horsepower is required at a speed of 62 miles per hour. It is at this speed that the aeroplanes should be flown to get the greatest endurance. If, however, it is desired to get

D. M. A. Aeronautical Library

The Aeronautical Information Branch of the Executive Section, Division of Military Aeronautics, has organized and will maintain a Library on aeronautic and related subjects. It is located on 3d Floor, Wing 1, Bldg. D.

This Library now consists of books on aviation, ballooning, engineering, radio, photography, metallurgy, and lubrication, besides dictionaries, handbooks, and general reference books.

About sixty periodicals, English, French and Italian, are regularly received and indexed. An annotated list of the more important articles is stencilled bi-weekly and sent to those interested. As many of the aeronautical magazines are not included in the periodical indexes now published, this service is found to be of value.

It is frequently found necessary, by the various sections of this Department, to compile technical data and to do research work of various kinds. Officers and civilians have spent much time on such work at the Library of Congress, the Smithsonian, and other Libraries. It develops that the same work is being done all the while by this Library. It, therefore, seems advisable to have the Library undertake all such service. Presumably it is more thoroughly and quickly done by those trained in Library work than by those unfamiliar with this profession.

It is planned to have books and periodicals to meet the requirements of all Sections. Requests for special material needed will be given prompt attention.

The Library is for the service of every Section and of each individual in the Air Service of the Army.

Air Service Citations Number Three Hundred Seventy-Four

Three hundred and seventy-four awards and citations have been issued to members of the American Air Service to date.

The Director of Military Aeronautics has just received a second list of Honors and Awards conferred upon American Aero Squadrons and flying officers of the American Expeditionary Forces. This list gives the citations of five squadrons, including the Lafayette, the 17th and 148th, which were with the British; the 90th and the 99th Squadrons. The names of fifty-nine American Flying Officers awarded the Distinguished Service Cross are recorded. Thirteen awards of the Croix de Guerre and three French citations are listed. One award of the British Distinguished Flying Cross is announced. The list of Italian honors conferred shows that thirty-nine American officers won the Croce al Merito di Guerra; six others were mentioned in Italian citations.

Distinguished Service Medals have been awarded to Generals Menoher and Patrick, and Legion of Honor Medals, Commander to Generals Menoher and Mitchell.

The list, together with the first list, which showed the citations of five American Squadrons, the 1st Day Bombardment Group and 129 Air Service Officers, brings the number of Air Service citations up to two hundred and fifty individuals and eleven organizations, not including over one hundred other awards of Distinguished Service Crosses announced by the War Department.

The citation of the Lafayette Squadron, formerly the Lafayette Escadrille, is signed by General Petain and reads as follows:—"Brilliant unit which has shown itself, during the course of operations in Flanders, worthy of its glorious past. In spite of losses which took away a third of its effectives, in a difficult sector, it has assured a perfect security to our Corps Observation airplanes, a complete service of reconnaissance at both high and low altitude, and the destruction, not only near the front lines but deep in the enemy's territory, of a great number of German airplanes and captive balloons."

The 17th and 148 Squadrons which served with the British Royal Air Force were cited in letters by both Generals J. M. Salmond and J. Byng, when they were transferred to the American Army. In citing the 90th Squadron, General Bell, Commanding the 33d Division says in part:—I wish to express to you at this time my appreciation for the valuable and efficient work your Squadron has done while serving with us. You have met all our requests with willing compliance unless prevented unquestionably by the elements. Your greatest cooperation has been in assisting us in locating our lines, which you have done repeatedly with uniform success and accuracy."

Attached to the citation is a list of the pilots of this squadron, as is the case of this citation of the 99th Aero Squadron, by Major General J. E. McMahon, in which he especially mentions pilots and balloonists as follows:

Captain William O. Butler, Germantown, Pa. Lieutenants James A. Healy, Jersey City, N. J.; Thomas J. Abernathy, West Pembroke, Me.; Sidney I. Howell, East Orange, N. J.; Arthur H. Jones, Hayward, Cal.; Lee M. Hurphy, Roxbury, Mass.; Ralph A. O'Neill, Nogales, Ariz.; Charles P. Porter, Beechmont, New Rochelle, N. Y.; Kenneth L. Porter, Dowagiac, Mich.; Joseph C. Raible, Jr., Hannibal, Mo.; Louis C. Simon, Jr., Columbus, Ohio; James E. Wallace, (Exam.ned) Atlanta, Ga.

The Italian Croce al Merito di Guerra was awarded to the following:

Major Florello H. La Guardia, New York City, N. Y., First Lieutenants James L. Bahl, Wooster, Ohio; Raymond P. Baldwin, Brookline, Mass.; Arthur M. Beach, Apalachin, N. Y.; Allen W. Bevin, Princeton, N. J.; Gilbert P. Bogart, 1219 N. State St., Chicago, Ill.; Arthur F. Clement, 606 Whitlock Ave., Crawfordville, Ind.; Wm. G. Cochran, Southold, L. I.; De Witt Coleman, Jr., Tenafly, N. J.; Kenneth G. Collins, Port Jefferson Sta., N. Y.; Alexander M. Craig, 79 Worth St., New York City; Herbert C. Dobbs, Jr., 221 B St., N. E., Washington, D. C.; Edmund A. Donnan, 115 Wade Ave., Washington, Pa.; Norton Downs, Jr., Threee Tuns, Pa.; Arthur D. Farquahr, Sandy Spring, Md.; Harry S. Finkenstaedt, University Club, Detroit, Mich.; Willis Fitch, West Medford, Mass.; Donald G. Frost, Paterson, N. J.; William O. Frost, no address; Gosta N. Johnson, Good Pine, La.; James P. Hanley, Jr., 110 Broadway, Wheeling, W. Va.; Geo. C. Hering, Felton, Del.; Wallace Hoggson, Greenwich, Conn.; LeRoy D. Kiley, 3227 Ellis Ave., Chicago, Ill.; Herman F. Krueger, Niosho Falls, Kan.; Paton MacGilvary, Madison, Wis.; Coble Mitchell, Grinnell, Iowa; William H. Potthoff, Logansport, Ind.; Aubrey G. Russell, no address; Wm. B. Shelton, Ithaca, N. Y.; Norman Sweetser, Philadelphia, Pa.; Emory E. Watchhorn, Los Angeles, Cal.; Frederick K. Weyerhauser, 509 North Yakima Ave., Lacoma, Wash.; Warren Wheeler, no address; Alfred S. R. Wilson, Santa Barbara, Cal.; Warren S. Wilson, 2063 Green St., San Francisco, Cal. Second Lieutenants Spencer L. Hart, Whitakers, N. C.; James Kennedy, Lansdown, Pa.; Norman Terry, Fulton, Ky.

New R. M. A.'s

In accordance with recommendations of the Training Section, the following-named officers are rated as Reserve Military Aviators, from the date set after their respective names: 1st Lieut. William Green, 1st Lieut. Aaron E. Jones, 2nd Lieut. Thomas J. Farrell, 2nd Lieut. Thomas C. Fitzhugh, 1st Lieut. James J. Donahue, 2nd Lieut. Jules D. Biscayart.

Air Units to Return

The following organizations have been assigned to early convoy: 16th Aero Squadron, 20th Aero Squadron, 227 Aero Squadron, 266th Aero Squadron, 353d Aero Squadron, 42nd Balloon Company 43d Balloon Company; 69th Balloon Company, 840th Aero Squadron, 488 Aero Squadron.

Recent Naval Orders

Lieutenant Louis C. Higgins, to duty as engineer officer, naval air station, Pensacola, Fla.

Lieutenant Rodman J. Miller, to Pensacola, report to commandant U. S. naval air station for dirigible instructions.

Captain D. C. Hanrahan. Northern bombing group, to post officer Danzig.

Lieutenant (junior grade) Le Roy C. Flino ordered to duty at office of Naval Operations Aviation, Washington, D. C.

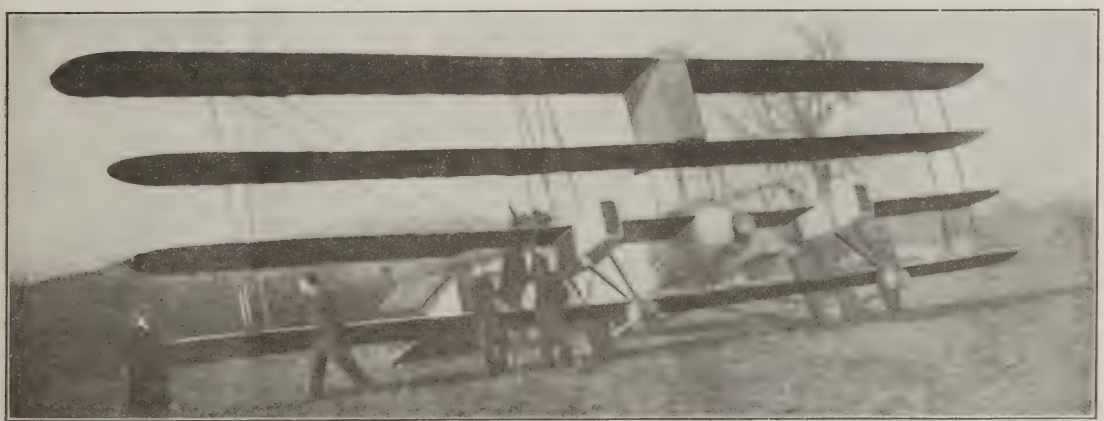
Lieutenant Commander Charles P. Mason, ordered to command flight of two F-5 boats to Pensacola, Fla., is revoked.

Commander John B. Earle, report to commandant, Naval Training Station, San Francisco, for duty.

Navy Takes Over Cape May Property

Three hundred and forty-nine acres of Cape May property which are now occupied by the Naval Air Station, the submarine base and barracks, have been taken over by the Navy Department.

Commander J. B. Patton, in charge of the Fourth Naval District, has notified property owners to remove all individual property from the tract.



The owners are asking a sum aggregating $4,000,000 for the land and if no agreement is reached with the Navy Department, a board of appraisers will determine the price to be paid.

Colonel Claggett Made Aerial Supervisor of Northwest Texas District

Colonel Henry B. Claggett has been appointed Aerial Supervisor of the Northwest Texas District. This district embraces the flying fields at Fort Worth, Dallas, Loanoke, and the balloon school at Omaha.

Prior to assignment to this duty Colonel Claggett was commanding officer of the Flying Department at Kelly Field. He is a West Point graduate.

Colonel Bruce B. Buttler will take Colonel Claggett's place as director of the Flying Department at Kelly Field.

FOREIGN NEWS

Colonel Leclerc Outlines French Aeronautic Plans

Paris.—*L'Excelsior* publishes an interview with Colonel Leclerc, who has been appointed to put into operation a scheme of aeronautic communication.

The type of aeroplane to be used for such service is under consideration, Colonel Leclerc's preference being centered on a four-motored biplane equipped with 800 horsepower motors, giving a speed of 800 horsepower and a carrying capacity of 1,800 pounds.

The planes will carry passengers, mails and commercial goods. The cost, Colonel Leclerc is convinced, of aerial journeys will soon be so reduced as to be no more than present railway fares.

German Politicians Receive Daily News By Aeroplane

Berlin.—The *Zeitung Am Mittag* is the first newspaper to employ aircraft for distribution. Its issues are being carried to Leipsig and Weimer, arriving far in advance of other Berlin newspapers.

Herr Ullstein, of the National Assembly, has arranged for regular newspaper delivery to the delegates at Weimer, having chartered several aeroplanes for the purpose.

Allied Aerial Superiority Annoys Bolsheviki

Archangel.—British and Russian aeroplanes flying low over the frozen timberland lying between the Vaga River and the Vologda Railway are seriously harassing the Bolshevik forces. In such operations, Allied superiority has proven a serious handicap to the enemy.

On February 9 Allied planes bombed the towns of Taresova and Shagovari.

French Firm Sues On Wright Patents

Paris, February 1.—The General Company for Aerial Navigation, which owns the Wright aeroplane patents in France, has resumed legal action against infringers of the patents with a view to having a claim to royalty on machines built on the principle of patents recognized.

It is understood that the company claims a royalty of 1,000 francs on every machine made since the beginning of the war. Its claims aggregate 30,000,000 francs ($6,000,000).

Fonck Made Captain

Paris—René Fonck was notified at a luncheon given in his honor by the Foreign Service Committee of the Aero Club of America that he had been promoted to the rank of Captain in the French Air Service.

Ambassador Sharp, who presided, stated he would not be surprised if Captain Fonck, after receiving a great welcome in the United States, would return to France by aeroplane.

Air Raid In Portugal

Lisbon—Two seaplanes of the Portuguese Republican Forces dropped proclamations on Oporto, the Monarchist stronghold and returned safely to their base, at Aveiro. En route, they bombarded and damaged the railway from Espinbo to Granjas.

Capt. Andrew Lang, R.A.F. and Lieut. Blowes taken after making a 30,500 foot altitude record

Market for Aeroplanes in Chili

According to official information transmitted to the British Board of Trade Journal by the British Consul at Valparaiso, there is a possibility that aeroplanes will be used to transport officials from the nitrate mines to the ports of export. At present a number of days are required to accomplish the journey, which an aeroplane can cover in a few hours.

It is stated that a local firm has already made application for representing as agents a well-known British aircraft firm.

Congressmen Make Cross-Channel Flight

Paris.—Representatives Patrick D. Norton of North Dakota and George White of Ohio returned from London to Paris by aeroplanes. They made the trip in two hours and twenty-five minutes.

American Representatives to Air Conference

Paris.—The International Aviation Conference, which is to be held in Paris in the near future, will have as representatives from the United States Brigadier-General Mason Patrick, Dr. F. W. Durand, of the National Advisory Committee on Aeronautics, and a naval officer. It is reported that Rear-Admiral H. S. Knapp will be the naval representative.

Zeppelins for Passenger Service

Berlin, February 13.—Several Zeppelins of a light type will be constructed for passenger traffic between Berlin and Switzerland, it was recently announced. It is planned to establish an aerial transportation line with them next summer.

Four Hours for London-Paris-London Trip

Paul D. Cravath, who was advisory counsel to the American Mission to the International Council on War Finance, made a record flight in a machine of the British Air Service Passenger Ferry. Leaving Hendon, a suburb of London, at 11 o'clock in the morning in a DeHaviland IV, equipped with a Rolls Royce engine, he was flown straight to Paris, arriving at 1:20 o'clock The return trip was completed in one hour and fifty minutes, making the over-all time four hours and ten minutes. Mr. Cravath did not go back to Paris on this trip. He was most enthusiastic as to the possibilities of rapid passenger transport by aircraft when interviewed by the press.

Air Invasions Dreaded

Paris, February 15.—In an interview with Professor Ferdinand Larnaude, Dean of the Paris Law Faculty and one of the French delegates on the League of Nations Committee, the fear of German treachery, particularly as to the possibility of a sudden aerial invasion of France, was given as the reason for France's insistence on a League of Nations which is potently armed. The Professor stated that it seemed quite within range of possibility for Germany to secretly prepare an aerial fleet which in one day could inflict terrific damage on the city of Paris.

Fireproof Petrol Tank Developed

London, Feb. 13.—A new petrol tank, which will neither leak nor catch fire when perforated by incendiary bullets, the *Daily Mail* says, has been added to the list of wonderful war inventions.

These tanks were being built and fitted in British aeroplanes as fast as possible when the armistice was signed. Had the fighting continued, British pilots would have been immune from one of the greatest causes of casualties.

This invention is to be applied to commercial aeroplanes.

England to India Flight Completed

London.—The Air Ministry announced that on January 16 the Handley Page machine, which started from England on December 13, arrived safely at its destination in India.

British Remove Flax Control

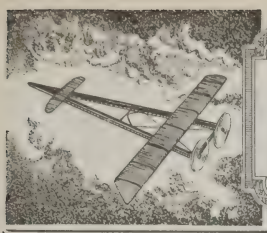
London.—The Flax Control Board announces the rescindment of the Flax Yarns Order, 1918, and the Flax Yarns Amendment Order, 1918, by which the Board's permission was required for the shipment of flax line or tow yarns both to and from Ireland.

British Air Ministry Well Represented at Peace Conference

London.—According to a semi-official announcement the Air Ministry is represented at the Peace Conference by thirteen delegates.

Record Paris-London Flight

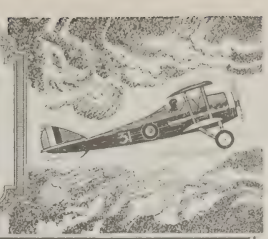
London, Feb. 13.—The British Air Ministry announces that a British service machine made a record flight between Paris and London, covering the distance in one hour and fifty minutes.



Make Good Time in London-Edinburgh Flight

At 3 a.m. on January 17, a Bristol fighter biplane, with Rolls-Royce engine, piloted by Major C. L. Payne, M.C., with Major C. Coe as observer, landed at Edinburgh, having flown up from London. Their actual flying time for the 400 miles was 3 hours 40 minutes, but a forced descent on the way, due to petrol trouble, increased the gross time to just over five hours. Considerable wind was met on the journey, and for most of the way the bright moonlight proved helpful. At the chief aerodromes on the route flares were lighted, and as the machine passed each station signal lights were fired from the machine.

14 Men Drink Wine, Play Cards, On Joy-Flight



London, February 11.—After flying from Paris to Croydon, an aeroplane with fourteen French officers aboard made the return journey, reaching Paris safely, says a copyright dispatch to the New York *Times*. The machine covered the non-stop journey of 200 miles from Paris to Croydon in 155 minutes.

The officers, despite the cold weather, wore their ordinary uniform without being protected by flying "warm." When the channel was reached a champagne luncheon was served aboard, and the officers smoked, played cards and altogether had an enjoyable journey.

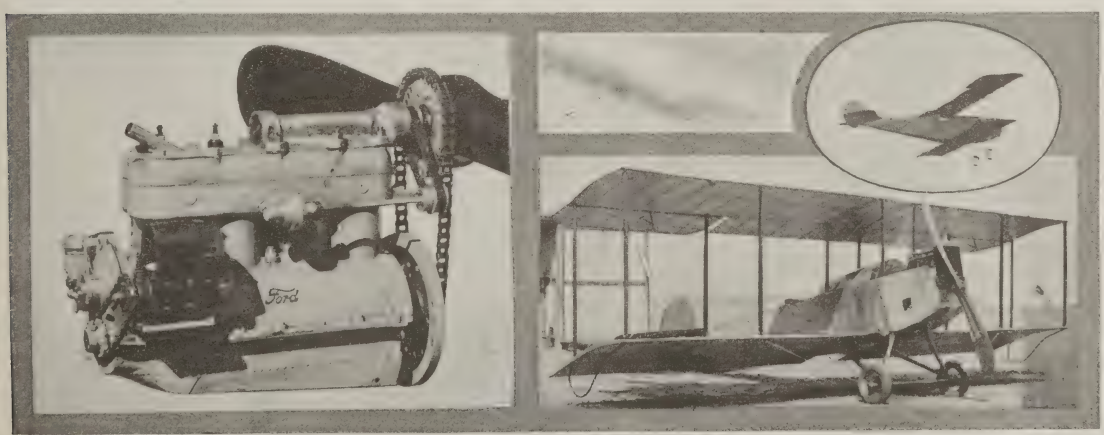
"Modern Aeroplane Building as a Step to Aeronautical Engineering"

IN conclusion to the series of articles titled "Model Aeroplane Building as a Step to Aeronautical Engineering" the writer feels that although a reader who has followed the articles from the beginning will not be an engineer in the strict sense of the word, he will have passed the rough stages of aeronautics and he will be in line for the more difficult studies to follow.

The author did not propose to develop a school-boy or an older beginner into an experienced designer of aircraft when he began these articles. He endeavored to merely give them a better and broader knowledge of aeronautics and to take a few technical formulas used for determining the performance of a machine and to transpose it into "easily understood by the average person" formula.

That these articles have done all that I expected has been proven to my satisfaction by the great number of letters and inquiries received daily pertaining to the calculations of aeroplane performance. In later articles I intended to go deeper into "Aeronautical Engineering" and show how to figure strains and stresses, strength of materials, sizes and dimensions of different parts to stand certain strains, in fact everything pertaining to Aerodynamics that I have not included in these articles.

Any student of Aeronautics who has followed this series from the very beginning and has constructed the models, gliders, and lastly the Ford motored Aeroplane is an aeronautical engineer and is entitled to call himself an engineer. Of course you know that to be known as "Engineer" it is necessary to win a "Degree" at some university and for that reason you cannot sign the big "A.E." after your name.



It is well to glance back a few years to the days before the aeroplane was a success and we see that old and young men alike were flying model aeroplanes driven by rubber bands, steel springs, compressed air, steam and gasolene motors, just as the model flyers of today are doing. The difference between those bygone days and model flyers of today is that they were working without any guide or figures and the flights of the models were for distances of about 50 feet while the aeromodelists of today have records and data to guide them, and the flights of some are upward of a mile.

Many of the old model flyers are today the best Aeronautical Engineers in the world, and have done wonders in the development of aircraft up to the present time.

So the model flyers of today can develop into the best "Engineers" of ten years from now and the field is large and profitable. You model flyers of today will see large aeroplanes capable of carrying tons of useful loads and many passengers arriving like the big steamships and the fast trains between our large cities. Even now aeroplane builders are in a neck and neck race to see who will be the first to cross the Atlantic Ocean and this I believe will be done by the first good aeroplane that attemps it, which will be as soon as the good weather arrives.

Not alone will there be these large machines but small fast pleasure and commercial planes as well and I might say here that there is plenty of room for improvement as the 100 per cent. efficient aeroplane is not in sight as yet and you, the young engineers of today, have a wonderful opportunity of developing something new and startling.

The accompanying illustrations of the re-designed Ford motor which shows how cleverly and compact a Ford motor can be made to give great power. This motor is the work of Mr. P. P. Bent, Fredonia, Kansas, and he has used it for four years in a Curtiss Pusher Type Machine. This motor has given a thrust of 340 lbs. actual test, with a seven-foot diameter, 5½-foot pitch propeller. The engine turning up 2,400 R.P.M. and the propeller running at 1,300 R.P.M. Mr. Bent is a garage man and has done considerable work and made many changes with the Ford Motor and he is now contemplating the building of the Ford motored aeroplane which was described on this page. In the aeroplane to the right of the engine the reader can clearly see the old style Ford radiator and just above it the aeroplane in flight. Mr. Bent flew all last season with this machine, being in the air close on to 800 hours.

Photographs of re-designed Ford motor and a one-seater aeroplane built by Mr. P. P. Bent, Fredonia, Kansas

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Nomenclature

(Unofficial)

Aerodynamics: At the bottom of the whole business.
Air Pocket: Look into any of our heads.
Angle of Attack: The difference between the way it ought to be done and the way we are doing it.
Angle, Gliding: Demotion.
Avion: Some of these days—MAYBE.
Drag: There ain't any such animal in the army.
Drift Indicator: Daily kuizzes.
Gap: Daily, or rather nightly, from 10 p. m. to 5:45 a. m.
Head Resistance: Self-evident.
Instability: Just before the academic board meets.
Lift: Money from home.
Lift-Drift Ratio: The difference between the coin we spend and the coin we earn!
Non-Skids: Hints from the bunch just ahead of us.
Nose Dive: To bust.
Pitch, To: To take a quiz without preparation.
Side Slipping: Women.
Stabilizer: They won't serve it to men in uniform.
Stalling: Doing it without an introduction.
Streamline Shapes: Queens.
Stringers: Most of the women we know.
Trailing Edge: About half of us.
Yaw: To yaw is to swing off the course. Week-ends.
Strain: Evidenced in our case by loss of weight.
Ultimate Strength: Graduation.
Work: Work is the overcoming of a resistance through a distance. Wings against heavy odds.—*Ohio State Pilot.*

ITS AN ILL WIND THAT BLOWS NOBODY GOOD

Someone's Little Mary visits Taliaferro Field
From *The Taliaferro Target*

In the Henhouse Sector

When Daniel Kramer's little black and white dog attacked a skunk in the chicken house at 5:30 A. M. on Friday, the canine was badly gassed, but he would not give up the fight until he had gotten his Hun.—Brighton News.

Not Anticipation

Some try breaking landing gears,
Others try the wheels;
But the biggest chance we seem to take
Is trying to eat our meals.

Looking Ahead

The year 1930. "All the air pilots put their machines in the hangars and refused to go on duty. Large numbers of City people were held up by the strike and had to make the journey to town by the electric trains. The strikers held a mass meeting in the Square, which was addressed by Mr. Dan Flyett, the President of the Union, who said that if the men's terms were not granted they would fly in a body to Washington."

Little Bo-Peep
Left one of her sheep,
To graze on the aerodrome;
An airman descending,
Caught Bo-Peep's sheep bending,
And that's why it didn't come home.

An Insinuation

"Well, Jones, do you like the Air Service, eh? Fine branch of the army, what?"
"Yes, sir! Fine life, sir."
"Ah, fine life! What were you in civil life?"
"In civil life—I was a soldier, sir."

Styles Change

Blue used to be "her color"
It suited cheek and brow,
But she makes up her complexion
So that khaki suits it now.

Technical Points

1. Never put more than 18 pints in the sump, or machine will wobble.
2. Try putting the prop on wrong way round. You will find it very easy to do stunts that way.
3. Always ascertain the amount of petrol in the tank by the aid of a match.
4. If the engine loses "revs" drop another penny in the slot, quick.
5. If an air leak occurs, fetch a plumber.
6. If misfiring occurs, fill magneto with shellac—this will make the spark stick.
7. If the engine is a "dud," fit a Ford.
8. If the engine drops out while flying don't get the "wind up." A J.N.4 can fly on its reputation.
9. If the engine is running rough, squirt carborundum paste into the cylinders. This will smooth things.

A Suggestion

Cadet.—"No, we must be firm, and stick to our determination not to open an 'Answers to correspondents' column. We will oblige you for once, however. When you join the mess, the best way to make yourself popular is to ingratiate yourself with your brother officers. You might even bring a little present for each; homeruns for the Wing Commander would do, and say Mr. Wells' latest novel, for the subs."

Maximum Service

(*Continued from page* 1173)

the greatest range, the most favorable speed will be indicated by drawing a tangent from the origin to the E.Hp. required curve, as at this point the most favorable ratio is attained between velocity and horsepower required.

In the example this speed is found to be higher than the speed for minimum power and is about 73 miles per hour. It will be noted that the tangent to the curve substantially conforms to the curve over the range of speed from 70 to 76 miles per hour. If the endeavor is being made to cover the greatest possible distance, it would be desirable to select the higher of these two speeds, for the reason that at the higher speed the controls would be more effective; the flight would be steadier; and also the flight would be accomplished in a shorter time.

As the aeroplane proceeds its weight will be reduced because of the consumption of fuel, and with a plane of heavy carrying capacity this reduction of fuel at the end of a long flight will appreciably reduce the load and thereby appreciably reduce the horsepower required for flight.

In the example chosen, I have indicated the horsepower required when all the fuel is used up, assuming a weight at this time of 4500 lb. In this condition the most efficient speed will again be indicated by a tangent to the origin, and in the example this speed is appreciably lower than that indicated for the full load condition, being anywhere from 55 to 60 miles per hour. At intermediate stages intermediate speeds will be found the best for the greatest range. This, therefore, indicates that in planning a long-distance flight due account should be given to this effect, as the radius of flight will be appreciably increased if proper account is taken of the influence of change of weight. To be exact, the tangent should not be drawn to the E.Hp. required curve, but to a set of curves which can be derived from these curves indicating the fuel consumption at different speeds and at different loads. The determination of the fuel consumption curves is a simple matter, but it would take more time and space than I consider it desirable to give in this paper. I can state, however, that the favorable speeds for long-distance cruising are not appreciably affected by using these fuel consumption curves in preference to the E.Hp. required curves.

The computations made in deriving the curves shown have been based on the Liberty engine, using straight drive. If it were possible to have available the same power with the geared-down propeller, it would be possible to greatly improve the propeller efficiency and thereby to improve the performance of the aeroplane indicated in the example. It is unfortunate that the geared-down engine is not available for general use, as the performance of practically every plane I know of using this engine in this country would be materially improved by its use. An inspection of the $\frac{V}{ND}$ efficiency plot will make this obvious. I also consider it unfortunate that in the development of the geared-down Liberty engines which have been produced, advantage has not been taken of the possibility of locating the propeller more centrally in relation to the engine group, because of the advantages which would be gained in streamlining. This engine is extremely awkward to streamline in its present form.

Design of Seaplane Floats

I will now proceed to the consideration of some of the elements of design of seaplane floats. The requirements of seaplane floats, because of the nature of their use, are necessarily conflicting, and the best that can be done is to make a compromise, bearing in mind these requirements.

The first requirement of a float is that it shall be seaworthy. This requires that the form shall be properly proportioned to provide good initial stability and a reserve of buoyancy. This is necessary to obtain a reserve of stability, as the seaplane must float without capsizing in a seaway and in strong winds. This requirement in itself conflicts with airworthiness and lightness and with the adoption of the best streamline form, which otherwise would be, in general, a form similar to a dirigible. It must be strong, but this naturally conflicts with being light. It must also have good planing qualities, and this requirement conflicts with streamline form. Airworthiness requires that it should have the minimum resistance and interfere in the least possible degree with the other characteristics of the seaplane.

In order to develop the best form of hull, the Navy Department began experiments at the Washington model basin late in 1911. These experiments were initiated by Capt. W. I. Chambers, U. S. N., with a view to the use of hydroplane blades, such as had been used by Forlanini, and to improving the planing qualities of the then existing types of floats. At that time the most successful float was that constructed by Glenn H. Curtiss, having a simple box section and a sled form profile. At the same time Burgess had developed twin floats having a single step, which had also proved successful.

One of the earliest experiments at the model basin was an attempt to reduce the wetted surface to a minimum by the use of a semi-circular section in the form of a half-cylinder whose ends were pointed like a projectile to reduce the air resistance and the water resistance. It was fortunate that this model was tried among the first, for its trials at once showed up a factor which later was discovered to be of the greatest importance, this factor being suction, due to downward curved surfaces when exposed to the contact of water at high speeds. It was at once realized that in the test of the floats due allowance should be made to represent the change in load carried by the float as the speed of the seaplane increased and the lift of the wings became an important factor, and all runs at the model basin had been made taking account of this and determining for each particular speed the "corresponding displacement" of the float. This was originally done by counterweighting the float so that the weight resting on the water represented that which would be the case taking into account the auxiliary lifting power of the wings. In the latest form of apparatus for testing at the basin this compensation is automatically made by the use of an inclined vane submerged in the model basin, which, by means of a system of pulleys, exerts a lifting power which is proportional to the lifting power of the wings at the speed at which the test is run.

In the tests with the semi-cylindrical model above referred to, it was found, as anticipated, that the resistance at low and moderate speeds was less than that experienced with other models, but as one-half of the speed for the getaway was approached, and therefore the float carried only three-quarters of the original load, it was found that the resistance of this model, instead of decreasing, increased; and that the model, instead of planing, as was expected, settled into the water and, finally, at the getaway speed, with no weight being carried by the float, but the float just in contact with the water, the influence of suction was so great that this model, instead of skimming the surface, proceeded to envelope itself in water and was drawn down so sharply by suction that its deck was flush with the surface of the water in the tank and great sheets of spray were lifted clear of the surface of the model basin.

As the work progressed the models of every known successful type of float were tried in the model basin, and data were collected as to the performance of these models. At the same time many experimental models were tried, and when these showed improvement over existing types, full-sized floats were constructed and tried out in actual flight. From these trials it was found that the conditions indicated in the model basin were duplicated in practice with full size, and it was seen that the model basin tests formed a means of predicting the performance of full-sized floats.

The steps of the Burgess floats were ventilated, and an investigation of this feature showed the value of ventilation for the step-type floats then in use.

All sorts of bow forms were tried and were shown to have very little influence on performance. The use of one, two, three and four steps was tried, and the indications were that there was little, if any, advantage to be gained by the use of more than two steps.

The introduction of the V-bottom showed promise of improvement, but it was early found that a V-bottom at the bow was invariably associated with large quantities of spray which would flow over the planes, and also, in a cross-wind would make the navigation of the seaplanes very uncomfortable. It was found by making the lines hollow at the bow that this spray could be held down close to the water, and in some later designs this hollowness was also introduced at the step apparently with beneficial results. After much experimenting it finally became apparent that the best form of hull was that embodying the single ventilated step, in which the after bottom rose at an angle of approximately 8 degrees to the bottom just forward of the step. The reasons for this are about as follows: With this type of float sufficient buoyancy can be provided abaft the step to eliminate the necessity of tail floats for stability. It was also found that by ventilating the step the water flowing under the forward bottom flowed over the step in the form of an inverted waterfall and that the contact of this inverted stream moved further aft as the speed increased and generally passed clear of the tail of the float just before planing was attained. At this point maximum resistance was encountered. After this point is passed the float proceeds to plane on the forward step, and because of the raised position of the tail of the float, it is then possible to vary the trim of the plane and change the angle of attack without again bringing the tail of the float into the water. Then progressively as the speed increases to flying speed the planing power of the portion forward of the step increases rapidly and the amount of wetted surface exposed to the action of the water is rapidly reduced, and the resistance of the float decreases, until finally at the getaway the water resistance of the float is eliminated.

The best results are obtained where the bottom of the float just forward of the step is substantially parallel to the axis of the seaplane. This portion of the bottom should have no curvature for a distance of several feet forward of the step.

Attempts were made to curve up the portion abaft the step with a view to producing a better streamline form for the hull, but this curvature was invariably found to produce suction, retard planing, and in many cases to augment the resistance of the float to such a degree as to require an excessive reserve of horsepower in order to get away. There was one case where a flying boat was built with very moderate curvature abaft the step, but on account of this curvature in the tail was unable to leave the water with a single passenger. Even though it could get up to a speed where the step itself was clear of the water, the tail would still drag and could not be drawn out of the water. By slightly modifying the tail of the float so that the lines abaft the step were straight, this same flying boat with the same powerplant was able to get off the water with a pilot and passenger.

One of the earliest floats tried at the model basin and built in full size was a twin float having a sharp V-bottom. The lines of this float conformed to the lines of a successful gunboat, and it was very pretty and clean in its action, but due to the influence of the curvature of the buttock lines at the stern, suction was present in this model and an aeroplane fitted with these floats, although able to get away with a pilot, was unable to get away with a pilot and passenger, there being insufficient reserve power to get over the hump.

Until very recently it was considered that so many inches of beam were required for every 100 pounds of weight carried by the float in order to attain planing, and this criterion has led to the adoption of the great beam found in the F-5 and H-16 and HS-2 models. But experiments with floats suited to carry 1,000 pounds each indicated that this model was remarkably satisfactory. The attempt was therefore made to enlarge this model in geometrical proportion to a 2,000-pound float, and the model basin results indicated this could be satisfactorily done. Another model was made of a 2,000-pound float and behaved satisfactorily. This same model was expanded to a 6,000-pound float, which behaved even more satisfactorily than the original. The lines of the N-9 float, which has proved successful in our training program, were developed from the original 1,000-pound float, although this float had less beam than the original full-size float which was unsuccessful. As a result of these trials, I now consider it to be conclusively established that once a satisfactory float is developed for carrying a definite load under given conditions, the same design can be used for larger loads by merely expanding the original lines in the ratio of the cube root of the displacement ratios.

In the design of the float for the NC-1 this principle was used and the model tested in the model basin, although only one-twelfth full size, gave data which indicated satisfactory performance. These data have been closely verified by the actual performance of the NC-1, though many designers were skeptical that this float could handle its load on so narrow a beam. This is no greater than that used in the F-5; the F-5 carries a load of only 13,000 as against over 22,000 pounds carried by the NC-1.

Attention is now invited to a series of curves showing the results of model basin tests on a number of different models.

Results of Model Basin Tests Compared

The dimensions of the floats and the seaplanes they represented were so different that to get a comparison it has been necessary to plot these results on non-dimensional scales. It will therefore be noted that the displacement of the hull is plotted as a per cent of the total displacement based on a per cent of the getaway speed. The resistance of these floats is indicated by a plot of the ratio of the displacement to the resistance; also based on the per cent of the getaway speed.

Based on the plot of model No. 2022, which is that of a successful H-12 boat, I have plotted the resistance and the horsepower required to overcome this resistance for the sample seaplane, the horsepower curves of which I have already explained, and I shall return to those plots in a few minutes. Before doing so, however, I wish to invite your attention to the plots of model Nos. 2081-A, 2081-B and 2081-C. You will note that the resistance of No. 2081-A was nearly one-quarter of the displacement at 40 per cent of the getaway speed; that the resistance of No. 2081-B was reduced to nearly one-fifth of the displacement at about 47 per cent of the getaway speed, and the resistance of No. 2081-C was between one-fifth and one-sixth of the displacement at about 52 per cent of the getaway speed. Also, the displacement in the latter case is less than in the preceding cases.

This change was brought about as follows: The original form of float had two steps, with curvature in the middle step and a rank upcurvature in the rear step. No. 2081-B represents this model with the rear step straightened, and No. 2081-C represents this float with straight lines for the bottom abaft the first step. It will readily be seen that the first modification was an improvement over the original, and the second modification was a still greater improve-

(*Continued on page* 1180)

ment. These models represent the model of the NC-1, and there is no doubt in my mind that if the original model had been used this seaplane could not have gotten off the water. Further, the influence of the curved portion at the tail of the float would have been so great as to cause the machine to squat so badly that the tail surfaces would have been caught in the stream of water rising from the tail of the float.

Let us now return to the horsepower curves. It will be noted that the resistance of this seaplane float reaches a maximum at a speed of 20 miles per hour, which speed corresponds to the point at which planing begins and, that there is a secondary hump at a speed of 40 miles per hour. The getaway speed is assumed as 62 miles per hour. The horsepower curve has been directly derived from the resistance of the float, and this horsepower must be compounded with that of the aeroplane progressing through the air. The horsepower required for this purpose is determined by taking the horsepower of the aeroplane at 62 miles per hour, which in this case is 150 E.Hp., and noting that the horsepower for the wings and head resistance is proportional to the cube of the speed. We thus derive the curve of the total air E.Hp. required for the seaplane, which must be compounded with the horsepower required for the float, thus giving us a total horsepower curve for the seaplane for speeds below the getaway speed; that is, while still in the water.

From an inspection of the horsepower curves it will be seen that the maximum horsepower for the float is required at a speed of about 23 miles per hour, and that this, compounded with the horsepower due to air resistance, requires 88 h.p. at this speed.

The horsepower for planing is very little exceeded by the horsepower available, so that it would take a relatively long time to pass through the planing condition; but, after this point is passed, the seaplane should accelerate rapidly because the reserve of horsepower available rapidly increases up to the getaway speed.

There is a secondary hump in the horsepower curve at 60 miles per hour just before the getaway is attained, but this secondary hump is of little importance, as there is an ample reserve of horsepower at this point.

As a matter of interest, I have investigated the improvement in performance which could be expected if a geared-down engine were used, assuming a ratio of 0.6; that is, the propeller turning at 0.6 of the revolutions of the engine. With this gear ratio a propeller 13 feet in diameter is indicated. Such a propeller at a speed of 80 miles per hour would show an efficiency of 73 per cent as against 69 per cent for the 9-foot diameter propeller. This gain of 4 per cent at 80 miles per hour would increase the climb by more than 11 per cent. It would have little effect on the speed, as the horsepower curve is very steep in this region. The improvement in efficiency at 20 miles per hour, although only 6 per cent, would mean an increase of 200 per cent in the reserve of horsepower to get over the hump in the horsepower curve at that speed. You will therefore see why in naval work the use of the geared-down propeller offers considerable advantage. The substitution of the geared-down Liberty for the straight-drive Liberty engines in the F-5 changes the top speed of this seaplane from 90 to 100 miles per hour and makes the getaway of this seaplane certain and rapid under all conditions, whereas the straight-drive propellers were only able to get this boat away in a calm with great difficulty.

The V Versus the Flat Bottom

Experiments have recently been made at the model basin on a series of models having different angles of V-bottom from the flat bottom up to a 20-degree V, and it is found that from a resistance point of view there is very little difference in the performance of the four models tried. So far as any advantage is shown, the deep-angle V has slightly the best of the argument. From a service point of view the deep V-bottom has many advantages; among them its remarkable shock-absorbing properties in taking care of bad landings, or in getting away and landing on a rough sea. The V-bottom also permits landing across the wind without serious retardation and without danger of capsizing sideways. This type of hull appears to absorb the shock by penetration and reduces the loads imposed on the bottom planking and on the framing supporting same. Due to this feature there is no need of carrying shock absorbers between the floats and the rest of the plane structure, and the lightest possible construction can be adopted.

The first hulls built in this country had an elaborate framework of ribs and longitudinals supporting the bottom planking, which afford a regular network having hundreds of intersections requiring fastening, and the fastenings themselves weakened the frames and the longitudinals at the point at which the frames carried concentrated loads on small areas of side grain. This type of construction was unnecessarily heavy and costly and was early abandoned in the construction of pontoons of navy design in favor of the longitudinal system of support.

In the longitudinal system of support the inner ply of planking is run athwartship and thereby constitutes a continuous system of ribs. This system is further reinforced by the outer planking run 45 degrees to the keel, which also acts as a continuous system of ribs, and these two systems transmit the water pressure as a distributed loading to the longitudinal members, which do not have their strength robbed by a series of notches. The longitudinals are arranged so that they collect the distributed load and concentrate it at points of support in athwartship bulkheads and these bulkheads in turn distribute the load to the keel, to the chine stringers, and to the deck planking. The keel itself is usually associated with a center longitudinal truss. Through these members the load is finally distributed to struts or directly to the wing structure.

On a large scale this system is adopted in the construction of the hull of the NC-1, which, although it embodies other features than those necessary to support the bottom planking, weighs only 2,600 pounds, while it carries a load of 22,000 pounds. This hull has demonstrated ample strength in landing on and getting off an 8-foot cross sea in practically dead air, where the landing and getaway were both made under the hardest conditions.

A controversy has existed for years as to the merits of the single float as compared with the twin float, but, based on the experience of our Navy with examples of both types, I believe that the central float with wing tip balancing floats is decidedly the best arrangement. In the central float system the loads can be concentrated on the point of support, whereas in the twin-float system the loads are usually concentrated in the center of the span and the wing structure has to be utilized to gain the necessary stiffness and necessarily has to be made heavier. In the center-float type, if a single propeller is used, it is located above the float and protected from the water, whereas in the twin-float type such propeller necessarily swings over the gap between the floats, which subjects it to punishment by spray and broken water. In landing a twin-float seaplane, unless both floats are landed at the same time, the second float invariably lands harder than the first, being slammed down on the water. Due to the greater lateral stiffness of the twin-float system, when getting off rough water the seaplane is forced to conform in its attitude to the form of the surface and wracks and lurches violently sideways unless going directly across the crest of the sea. In maneuvering in the air, also, the separation of the twin floats adds considerably to the inertia about the longitudinal axis and makes the action of the ailerons less effective. With twin floats, when taxi-ing across a strong side wind, the lee float must have at least 100 per cent reserve buoyancy, and this leads to greater weight than is necessary with the single center-float providing the same stability.

Types of Navy Planes

As above referred to, the principal types of service planes used by the Navy were the HS-2, H-16 and F-5. Your attention is invited to the illustrations of same.

The HS-2 was developed from an original twin-motored seaplane designed for the Army, which, however, did not prove successful. It was originally intended to be used with two 100-hp. engines. Later, when the Navy took hold of it, the Curtiss VX3, a 200-hp. engine, was used, and this seaplane gave a fairly satisfactory performance with this powerplant. At about the same time the Liberty engine became available, and as soon as it was installed it was found that this performance was very much improved and this seaplane was capable of flying at a total weight of about 5,900 pounds. On this basis it was then attempted to convert it into a military machine by providing the necessary guns, bombs and other equipment. After everything had been added, it was found impracticable to carry the military load desired on a limit of 5,900 pounds total weight. The expedient was therefore adopted of adding wing surface, and the original HS-1 thus became the HS-2, capable of carrying a load of 6,500 pounds, with practically no reduction in full speed and with considerable increase in climbing power. Many forced landings have been made at sea; some due to powerplant difficulties, such as stoppage of fuel supply, or failure of the engine or propeller, and sometimes due to head winds forcing a landing on a return trip on account of exhaustion of fuel. Although many of these landings were made under bad weather conditions and in rough seas, in nearly every case landings were accomplished without serious damage to the hull.

The general arrangement of this seaplane is indicated in the illustration. The pilot and assistant pilot are seated in a cockpit just forward of the wings, from which point they have a good view for the operating of the seaplane. A radio outfit is provided just forward of the pilot. A gunner's cockpit is fitted in the bow, and this cockpit is provided with a gun ring and Lewis gun. This gunner has a very good range of fire, particularly ahead and down and on either beam; also upward and to the rear above the planes. But there is no means of firing abaft the beam, and this boat is unprotected against attack from the rear. In the gunner's cockpit are also fitted the bomb pulls and the sight for dropping the bombs, which are located under the wings just clear of the hull. On account of its undefended condition against attack from the rear, this seaplane was not used in sectors where it would be exposed to attacks by enemy aircraft, but there were many places abroad—and, of course, in this country—where no such attack was probable and where this seaplane proved particularly useful in submarine patrol and convoy work. This seaplane is also used for instruction purposes as an advance step toward handling the regular twin-motored seaplanes. The HS-2 was provided with a single Liberty engine and a pusher propeller, and has very satisfactory air maneuvering qualities.

The H-16, as you will see, was a twin-engined seaplane with a flying-boat hull, using tractor propellers. The pilot and observer are seated in a cockpit about half-way between the bow and the wings, where they have an excellent view. The H-16 was also fitted with a gunner's cockpit the same as the HS-2. In addition, a wireless operator was carried inside the hull just forward of the wings and back of the pilots. Abaft the wings an additional gun ring was fitted covering the arc of fire above and between the wings and the tail controls and to take care of the region to the rear and below the tail controls; gun mounts were also fitted, swinging on brackets through side doors in the hull. The bomb gear was operated from the forward gunner's cockpit and four bombs were carried, two under either wing. This type of boat proved very serviceable, and was a substantial copy of the same type of boat built in this country for England, differing only in minor details from those supplied to England. This boat was really a successor to the H-12, which was very similar, except that the hull of the H-12 was more like that of the HS-2 both in construction and in the form of the planing fins.

As you will note, the F-5 is very similar to the H-16, being approximately 10 per cent larger than the H-16. In addition to this increase in dimensions, which was made to afford a greater military load, it will be noted that this seaplane had balanced wing tip ailerons and also a balanced rudder. The hull form is practically identical with that of the H-16. The principal data of all three of these boats will be found in the appendix of this paper.

A little over a year ago the Navy Department decided to build a large seaplane equipped with three Liberty engines and, after consultation, a contract was entered into with the Curtiss Aeroplane & Motor Corporation and a design was developed, under the supervision of representatives of the Navy Department, first at the Austin Street plant of the Curtiss Corporation in Buffalo and later at the Garden City plant of that company. As a result, the NC-1 was developed and built and has recently undergone trials at Rockaway Beach.

It will be noted from the illustration that this seaplane is neither a hydroplane nor a flying boat. It may be considered a compromise between these two types. The three engines are arranged as tractors in separate nacelles placed between the wings, and the pilot and assistant pilot are located in a cockpit just abaft the center motor. A gunner's cockpit is located on top of the center plane, another gunner's covkpit is located in the bow. The tail is of the biplane type and supported by hollow spars in an inverted pyramidal form of structure resting on the stern post of the hull. The pilot and observer have an entirely satisfactory view for general maneuvering and for landing and getaway. It was contemplated that additional gunners would be placed in the after portion of the hull with guns mounted on brackets so that they could cover the arc of fire from the beam to the stern and downward; also that this seaplane would carry a number of bombs, together with a non-recoil gun of large calibre at the bow. Three more of this type are under construction, and advantage is being taken of the opportunity to make a number of changes which it is believed will improve performance over that of the original.

Future Developments

I have been asked to incorporate in this paper some remarks on the future developments for the Navy, but as these more properly come under the subject of operations of the Navy, on which subject we are to hear from Commander Towers, I shall limit my comments to the statement that the Navy Department fully appreciates the desirability of experimenting with a view to improving existing types and the development of new types of seaplanes and aeroplanes, directed to the solution of those problems which have arisen in the war and, more particularly, to the development of seaplanes or aeroplanes for operation with the fleet. This development, as I pointed out at the beginning

MARTIN BOMBER

The Bomber Performance Demonstrates Military Supremacy

The Martin Plane is First to Fulfill Commercial Requirements

Our Freighter and 12-Passenger Airplane soon to be announced

THE GLENN L. MARTIN COMPANY
CLEVELAND

Contractors to the United States Government

of this paper, was naturally set aside because at the time of the entry of the United States into the war the lines on which development was most badly needed were already pretty definitely determined and there was almost no need of aeroplanes for operation with the fleet. I believe that much larger seaplanes are possible and will probably be found useful for naval work, and development on these lines may reasonably be expected.

This paper has already reached too great a length for me to enter into the subject of structural design, which is a very broad subject in itself. It is a matter of interest to know that so far as this branch of aeronautic engineering is concerned, very satisfactory progress has been and is being made, and along these lines some of the greatest improvements in the near future may be expected. So far as aerodynamic engineering is concerned, wind-tunnel experiments and full-sized experiments have now brought this branch to a very satisfactory state, so that the performance of a new design can be very definitely determined, even before construction is begun. So far as the engineering features of float design are concerned, I believe important progress has been made through the demonstration that model basin data can be accurately applied to full-sized design.

Book Reviews

The Skyrider: Compiled by B. M. Bower. This up-to-date narrative of ranch life will thrill and amuse every lover of western stories. The humor that characterized the "Flying U" stories is again to be found in "The Skyrider." Its refreshing variation—the introduction of the aeroplane—should make this rank high in popularity among the B. M. Bower books.

Johny Jewel, of Rollong R. ranch in Arizona, is so obsessed with the idea of flying that, to the amusement of the other ranchmen and to Mary V., the winsome daughter of ranch-owner Selmer, he expresses his ambition in poetry. To assist him in his duty at Sinkhole Camp of preventing outlaws from rushing Rolling R. horses over the border into Mexico, Johnny purchased a damaged aeroplane from a "greaser," who promptly proceeds to steal some of the choicest of the Selmer stock. So absorbed was Johnny in his task of repairing the damaged plane, for which purpose he had enlisted the assistance of a stranded aviator of dubious character, that the "greaser" was able to escape unchallenged. Confronted with the loss by the owner and chagrined by his negligence, Johnny in his aeroplane seeks out the missing horses. There are tense moments of excitement and danger, involving encounters with outlaws, and Johnny escapes with his life.

This book can be purchased at The Aeronautic Library, Inc., 299 Madison Ave., N. Y. C. Price, $1.55 postpaid.

"The Aeroplane": compiled by A. Fage. On account of the rapid advancement in aeronautics, the author has been forced to bring out a revised edition,—the fifth edition—of this publication. In this volume there is explained comprehensively the following: air resistance, wind velocity, distribution of pressure around cylinder and streamline bodies, struts, design and construction of wings, front or main spars, aeroplane fabrics, construction of various types of aeroplanes, namely Bristol 80 H.P. Tractor Biplane, Sopwith Bat-Boat, Sopwith 100 H.P. Hydroaeroplane, Avro Biplane, Blériot Monoplane, Nieuport Monoplane, Wright Hydroaeroplane, etc.,—the equilibrium and stability of an aeroplane, the design, construction, aerodynamic theory, performance and stresses of the two-bladed and four-bladed airscrews, and several modern aeronautical motors, such as: 120 H.P. Argyll, 120 H.P. Beardmore Austro-Daimler, 200 H.P. Salmson, 100 H.P. Grome, Monosonpape types, 100 H.P. Green, 300 H.P. Green, 135 H.P. Sunbeam.

In addition to above mentioned data, there is other miscellaneous material, which will prove of much value to the technical man interested in aeronautics.

This book can be purchased at The Aeronautic Library, Inc., 299 Madison Avenue, New York City. Price, $3.25 postpaid.

The Flying Fighter: Compiled by *Flight*. No branch of Uncle Sam's service is so alluring as aviation. And what greater hero can there be than the birdman who hunts the Hun through the clouds and risks his life in all manners of thrilling and dangerous maneuvers? This is a story of a skilled American air-fighter, who has the most exciting adventures dropping bombs on Ostend, chasing German raiders over London, spotting submarines and battling with the enemy 18,000 feet in the air. It gives a vivid picture of life on the western front as thousands of our boys have seen it.

Following is a list of the contents I Off for Canada; II Young Airmen; III Learning to Fly; IV Aerial Gunnery; V Final Training; VI My First Reconnaissance; VII An Air Raid on Belgium; VIII Contact Patrol; IX Artillery Observation; X Aerial Photography; XI Coast Defence Work; XII Repelling Zeppelin Raids; XIII Night Flying; XIV My Last Air Battle; XV Back to New York.

This book can be purchased at The Aeronautic Library, Inc., 299 Madison Avenue, New York City. Price $1.50 postpaid.

Sunstedt-Hannevig Seaplane

(*Continued from page* 1162)

run out with a small piece of spruce between, serving as a very flexible trailing edge, greatly increasing the stability and gliding efficiency of the machine.

The lower plane is entirely constructed of solid ribs, with a chord of 8'-0". The wing ribs are cut out of a special three-ply veneer, with lipped ends, fitting closely into the boxes of the I-beams, and fastened in place by means of two cap strips, glued, nailed and screwed to the webs and wing spars.

At the points of fastening the interplane struts to the main spars of the wings, there is an internal steel compression tube, reinforced at the ends, bolted in place, and sockets fastened directly to the main spars, interbraced diagonally with solid steel wires fitted with turnbuckles for adjustment and locked, taking up all of the drift and other strains on the wings, and subjecting the wing ribs to the one purpose of lift only.

The ailerons are of strong construction, located at the wing ends, and hinged to the upper rear beam by means of eye-bolt hinges.

The wing section used in the U. S. A. No. 5, which is especially designed for high speed and great lift, serving as a medium between a scout and an extra heavy lifting wing, and, as well, has high structural safety factors.

The interplane struts are all made of seamless steel round tubing, streamlined with Balsa wood encased in linen, and the struts with reinforced ends are fitted into sockets which are bolted to the main spars of the wings by four nickle steel bolts straddling the wing spar to tie plates on the opposite side of the spar.

All brace wires in the wing cellule are Roebling stranded steel cable, doubled where necessary, and attached in the most approved method to shackles and turnbuckles. Control cables are of flexible cable, and all internal wing drift wires and fuselage wires are of solid steel.

Tail Assembly

All of the tail surfaces are built up of steel tubing and wood spars, with laminated ribs and spruce cap strips. They are all covered with linen and treated with dope and then painted, as are also the wings.

The control is by standard methods of arms and cables, and the bracing of the tail is such as to make a very rigid construction. The horizontal stabilizer is adjustable to correct for uneven loadings when necessary.

Here It Is—The Practical Aeroplane

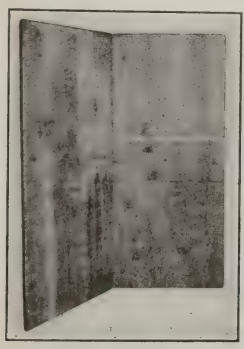
Pioneer History of Water-Proof Ply-Woods

Its development in America by the Dodge Manufacturing Company, as applied to

INDESTRUCTO Products

Indestructo Globe Trotter Trunk built in 1904 of water-proof ply-wood



Indestructo bottler's case patented in 1904—built of water-proof ply-wood

THE process of wood lamination or wood veneering dates back to the time of Pliny in the days of the Roman Empire, at which time it was quite generally used on fine furniture.

While the present process is a common one to wood workers, the scope of the practice was until 1904 limited, on account of the failure of known glues and cementing processes to hold under all conditions of atmosphere and contact with moisture.

In 1904, coincident with the growing necessity for the conservation of timber, came the discovery of the Indestructo ply-wood process, and its introduction to the American markets by the Dodge Manufacturing Company, as the first water-proof ply-wood that had been offered for commercial use in this country.

Large water-proof seven ply panels built for table tops in 1908

No branch of forest utilization, with the possible exception of pulp wood has shown such rapid development in the last ten years as the veneer industry as a whole.

In 1905, 132,800,000 feet of logs were used by veneer makers, but as the amount of timber cut from the log averages about 20% greater than the logs measure, it is safe to say that the timber used for veneer stock would have made more than 166,000,000 feet of ordinary lumber.

Until the discovery of the Indestructo process, only a few of the hard woods were available for use in laminated woods.

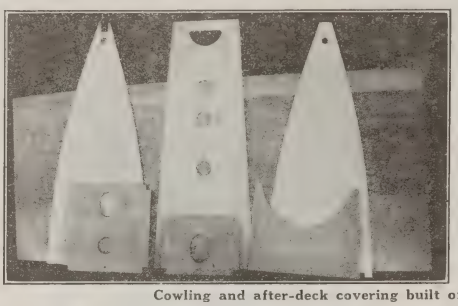
By the Indestructo process all woods except those containing resinous sap can be utilized in the manufacture of water-proof, weather-proof multi-ply construction.

In 1904 the first commercial product manufactured of water-proof ply-wood was placed on the market; this was the famous Indestructo trunk made by the Dodge Manufacturing Company of Mishawaka, Indiana, and of which there have been 275,000 sold in the last fourteen years.

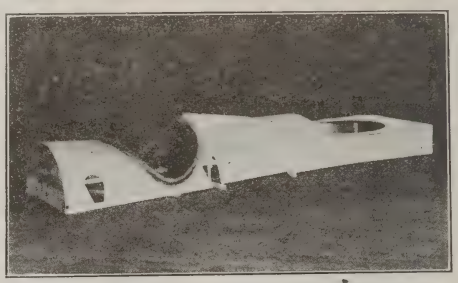
Heretofore the "Veneering process" had been largely applied to fine furniture, pianos, interior finishing, etc. Quite naturally the Dodge Manufacturing Company, after its acquisition of the veneer process, searched the available commercial fields for the exploitation of ply-wood as a substitute for solid woods for utility purposes.

The Indestructo bottler's case was developed in 1907, and sold by the hundred thousands to brewers all over America.

This was one of the most difficult and exacting usages to which ply-wood had ever been subjected.



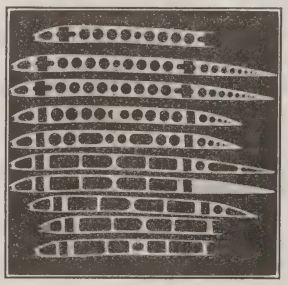
Contact with moisture, steam and spirits in bottling houses constituted a test that proved beyond a shadow of a doubt the adaptability of Indestructo ply-wood for such purposes.



During that time the ply-wood manufactured by the Dodge Manufacturing Company had been made and sold on water-proof guarantee since 1904.

It had been subjected to the most unusual tests, of which the most notable perhaps was the construction in 1916 of a large sign board, 30 feet long by 12 feet high, erected near the plant for advertising purposes.

The face of this board consisted entirely of three-ply veneer, protected only by paint against the elements.



That the board is standing today in its original condition is sufficient evidence in itself of the durability of the product made by the Dodge organization.

Cowling and after-deck covering built of Indestructo ply-wood for DeHaviland Fours

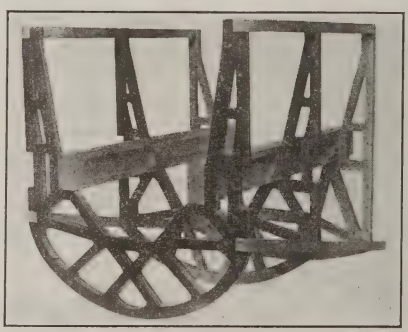
In 1908 the Dodge Manufacturing Company installed in the new mill of Hecker-Jones-Jewell Milling Company of New York, 20 flour receiving bins, 50 ft. high and 4 ft. in diameter, and holding a slipping load of 30,000 pounds of flour each. These receptacles superceded the use of the old style stave and steel equipment, because of their freedom from sweating and caking of flour on the inside surface and as a protection against vermin.

Ply-wood wing members for De-Havilands

These bins are in operation today, and are in as good order as when they were put in eleven years ago. This same installation included the housing equipment for 112 roller mills.

In 1906 the first ply-wood barrel was constructed.

A striking feature of its pioneer construction was its lightness and the elimination of leakage, as well as the unit head.



Safety covering for factory machinery, all types of trunks, laundry hampers, meat carriers, delivery boxes, heat deflectors and wall covering followed the process of engineering development up until 1916 when the attention of the Government was first directed to the necessity for water-proof ply-wood to be used in airplane and dirigible construction.

There is no doubt in the minds of the commercial world as to whether or not the Dodge Manufacturing Company made the first use of water-proof ply-wood in America.

There is no doubt in the minds of the users of Indestructo trunks and other products since 1904, that the material used in the construction of these products was actually of the water resisting type, and embodied maximum strength with minimum weight.

In 1917 the United States Government first experimented with ply-wood for use in aeroplane construction.

The Dodge Manufacturing Company taking the initiative, immediately placed its entire organiza-

tion of engineers and practical mechanics at the disposal of the Government in working out a suitable basis upon which ply-wood could be produced in great quantity for such uses.

land 4's, working in conjunction with the Dayton-Wright Aeroplane Company of Dayton.

Press capacity was immediately increased to meet the demands of the Government, and thou-

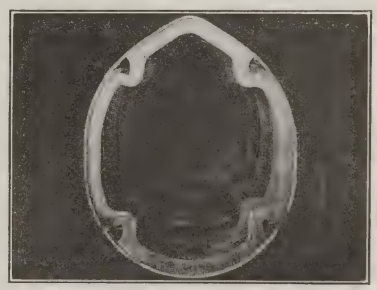
adaptation of tests and standards by which the facilities of wood workers in other lines might be adapted to the intensive production that was required.

During the period of the war the Dodge Manufacturing Company constructed cowling, afterdeck covers, wing beams, ribs and engine bearers, for the De Havi-

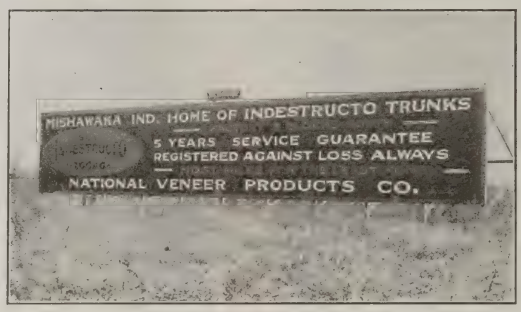


tractors of aircraft, working on Government contracts.

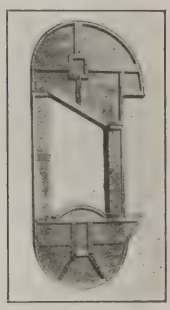
In the Fall of 1917, the Bureau of Naval Construction and Repair of Washington submitted drawings from which samples were to be built and tested, covering transverse girders and other frame members for dirigibles.

After considerable

Monocoque fuselage built without cross wires or interior bracing

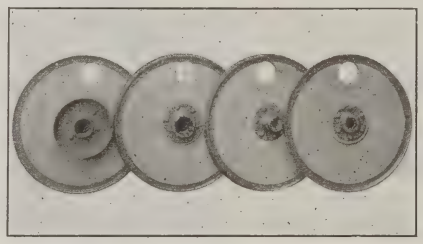


End view of Monocoque fuselage



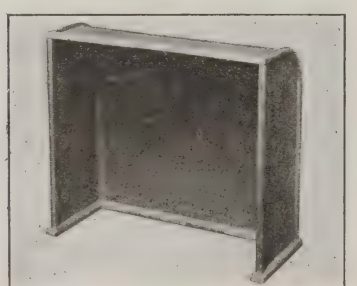
study and experiment at the Dodge plant, a triangular girder was built, a three-foot section of which, weighing 12 ounces per foot, finally broke under a total pressure of 22,600 pounds, or 6,027 pounds per pound of weight.

Flour mill boot made of ply-wood with butt joints affording smooth interior surface



Ply-wood sign board exposed to weather protected only by paint

Ply-wood safety covering for Band Saw

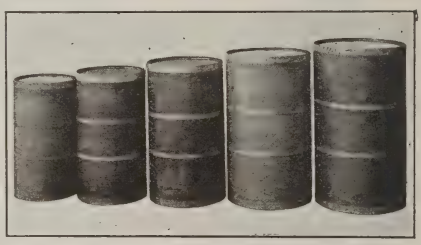


Photographs accompanying this article on the opposite page, show the girder and the hydraulic press used in testing.

The first Monocoque fuselage built in this country was submitted to the Government early in 1917. This fuselage was built without cross wires or bulk heads, the strength of the whole structure being carried by the skin and laminated longerons, as illustrated on the opposite page.

Motor car wheels built of heavy ply-wood

In addition to the manufacture of aeroplane parts, the Dodge Manufacturing Company designed and constructed field container and shipping cases for the Lewis machine gun and balloon trunks of considerable size for the Goodyear Tire & Rubber Company.



Heat deflectors for hot air registers

The files of the Dodge organization are filled with hundreds of testimonials from users of Indestructo products that prove conclusively the general satisfaction that has been experienced in the last fourteen years from the use of Indestructo ply-wood.

Considerable literature has been issued from time to time by the Dodge organization and is available to those requesting it.

The war is over, and while the demand for aeroplane parts constructed of ply-wood is in suspension pending the rearrangement of the industry to meet the peace-time program, the wheels of the Dodge plant are turning just as busily in the production of their regular ply-wood products as they were before the interruption caused by the war.

Ply-wood barrels of progressive sizes for nesting during return shipment

The demand for Indestructo trunks, hampers and other products is greater today than it has ever been, and one need only step into the highest-class trunk-selling store in any city to learn once and for all how highly Indestructo-made goods are regarded by dealers and users throughout America.

From the position of pioneer to that of leadership, covering a period of fifteen years, each filled with study, experiment, failure and ultimate success, the Dodge Manufacturing Company have found a satisfaction in the development of Indestructo ply-wood products that fully measures up to the accomplishments of Dodge products in other lines.

Dodge equipment for the mechanical transmission of power is known the world over for its quality, standardization and reliability for the service intended.

And we point with pride to our final record of achievement in the ply-wood industry as being the highest recommendation of the Dodge reputation as engineers.

VOL. VIII NEW YORK, MARCH 3, 1919 NO. 25

AMERICAN AERONAUTICS' GREAT FUTURE

AMERICAN aeronautics has a great future. It only requires the proper impetus to start the different aeronautic activities.

This impetus is to come through the combined results of the Aeronautical Exposition being held at Madison Square Garden and the 69th Regiment Armory and the Aeronautic Convention and aerial contests to be held under the auspices of the Aero Club of America, the Aerial League of America and the Pan-American Aeronautic Federation in May.

Substantial results are assured from these successive events. The present exposition will show the aircraft produced in the United States during the past year. The aerial contests to be held in May will show in operation the aircraft which are ready for sport, aerial transport of mail, express and passengers, exploration, aerial forest patrol, meteorologic research, and other utilitarian purposes, as well as the military and naval aircraft.

The Aeronautic Convention is to bring up for consideration every important phase of aeronautics and is to be attended by hundreds of authorities from all over the world and, it is expected, by thousands of people. The plans for both the contests and the convention, which are to be announced in a few days, are most extensive and promise to answer the questions which thousands of people have been asking during the past three months regarding the future of American aeronautics.

Whenever we have stated that American aeronautics has a great future and that the "peace" aeronautic movement would soon be established on a substantial basis, scores of people have asked:

"When and how will these aeronautic activities start? Will these activities start on time this year to partly fill the gap in the aeronautic industry caused by the cancellation of war orders?"

The extensive use of aircraft for sport, pleasure, aerial mail carrying and aerial transportation of express and passengers are some of the most substantial developments to be expected in the United States this year.

Latin-American Missions coming to Air Contests and Aeronautic Convention.

Lack of time in which to get here prevented the Latin-American missions from coming to the United States for the present exposition. But they will be here for the Contests and Aeronautic Convention to be held in May. The twenty Latin-American republics need aircraft for their military and naval schools as well as for aerial transport of mail, passengers, express and products. There the aircraft promise to solve difficult problems of transportation. These problems are also to be discussed at the convention in May, and the Latin-American commisisons will be given the opportunity to see in flight the aircraft which are to solve the problems under discussion.

Remarkable Opportunities

"Permit me to urge that you bring to the attention of the country the fact that today aeronautics offers even greater possibilities than the railroad field did to the Vanderbilts, Harriman, Hill, and other great railroad builders. The world is ready for aerial transportation and the men whose foresight leads them to put their efforts in establishing air lines will find aeronautics to offer greater possibilities than were offered by any other line of human endeavors."

Thus Rear Admiral Peary, one of the energetic and progressive leaders of the aeronautic movement, summarized the splendid prospects for the employment of aircraft for transportation and other utilitarian purposes in his message to the Aero Club of America last week.

Like Mr. Alan R. Hawley, the progressive president of the Aero Club of America, and Mr. Henry A. Wise Wood and Admiral Fiske, Admiral Peary is in a position to know the exact status of American aeronautics. To these men, who have so ably led the American aeronautic movement in the past eight years, the country turns for advice and leadership. We know that the daily time of these able leaders is occupied by the hundreds of people who are becoming interested in the aeronautic movement from different standpoints and who go to these leaders for advice and guidance.

Their expressions of opinion are based on knowledge of public interest in aeronautics as well as on years of experience and sound judgment.

Their leadership and foresight was proven wise and sound in the past years and their efforts in training hundreds of aviators at private expense in 1915, 1916, 1917 gave the United States Army and Navy 300 aviators who were the first to be sent overseas, where they gave a good account of themselves.

These leaders have been the people who have maintained an optimistic attitude regarding the immediate future of American aeronautics during the past few months, and have prevented the spread of pessimism which was rampant for a time.

172 Orders for Aeroplanes Secured by an Aerial Age Advertiser

We see a great many evidences of public interest in aeronautics. One of the most forceful evidences was the experience of a manufacturer, an AERIAL AGE advertiser, who received 172 "line" inquiries from prospective buyers of aeroplanes in response to his advertisements in AERIAL AGE and *Flying*.

Some of these inquiries are from aviators who have left the service; some are from people who would like to use the planes for pleasure and transport in the United States; some are from South and Central America and Canada. A score are from substantial business concerns who desire to secure the agency for this type of aeroplane.

This is only one of scores of similar indications of the fact that public interest exists and we only need proper impetus to start American aeronautics on a substantial basis.

LIQUIDATING 24,000 CONTRACTS

MAJOR GENERAL CHARLES T. MENOHER, Director of the Air Service, in his message to the Aero Club of America said, in part:

"On assuming charge of the Air Service I find the following conditions existing: Due to the signing of the armistice and to the orders to demobilize as rapidly as possible, the Bureau of Aircraft Production is engaged in the cancellation and settlement of some 24,000 contracts, agreements, and so forth, of all kinds, and the disposal of a large amount of surplus material on hand—in fact, in a general liquidation of its business. The policy being pursued in this matter is to settle these contracts as rapidly and as liberally and equitably as is possible, consistent with the interests of the Government; and to dispose of surplus property and material at as a good a price as possible, but gradually, so as to disturb the market in any commodity that is offered for sale as little as possible. Although the best talent in the Bureau is now engaged on this work, it all takes much time."

A report from Washington states that aircraft contracts aggregating $468,847,993 have been cancelled by the War Department. The cancellations were distributed as follows:

Engines and spare parts	$250,107,551
Planes and spare parts	163,231,790
Chemicals	13,181,285
Balloons and balloon supplies	9,877,356
Instruments and accessories	9,864,238
Fabrics, lumber and metals	5,954,726
Miscellaneous	16,631,047
Total	$468,847,993

Altogether 20,147 Liberty motors have been produced, and 331 are still on order. When the armistice was signed there were 30,526 on order, and since that time contracts for 23,622 of these have been cancelled. From November 11th to February 7th deliveries totalled 6,573, distributed as follows: Nordyke & Marmon Co., 548; Ford Motor Company, 897; General Motors Corporation, 927; Packard Motor Car Company, 1,473, and Lincoln Motor Corporation, which was built with Government money specifically for the production of Liberties, 2,728.

Exclusive of 204 shipped without motors, the United States had produced 4,600 Haviland 4s. There are still 42 on order. Deliveries between November 11th and February 7th were 61 from the Standard Aircraft Corporation, 631 from the Fisher Body Corporation and 681 from the Dayton-Wright Aircraft Company.

May Sell Surplus Property in Adjustment of Contracts for War Supplies Without Reference to Sales Director

The War Department publishes the following supply circular issued by the Director of Purchase, Storage and Traffic:

"The bureaus of the War Department are hereby authorized to sell without further reference to the Director of Sales, any surplus property covered by the act of July 9, 1918, and War Department Bulletin No. 1, 1919, provided:

"(a) That the sale or agreement to sell is made as an incident to the contract for war supplies or the settlement of such a contract which has been suspended or reduced, and has the approval of such contracting officer, board, or higher authority, as may be required to approve such contracts or settlements, and

"(b) That the proper sales officer or board of the bureau shall be consulted as to the terms, conditions, and advisability of the sale or agreement to sell.

Full Report Required

"A full report shall be rendered to the Director of Sales, office of the Director of Purchase, Storage and Traffic, immediately upon the completion of each such sale, showing the character of the property sold, to whom sold, the price received therefor and the purpose for which sold.

"It is believed to be of advantage to the Government in the settlement of any contract to have the contractor retain as much as possible of the property involved, provided he will take it at a fair price. Any property that can not be disposed of in this way becomes surplus and should be turned over to the Director of Sales for disposal. The Director of Sales is at all times ready to take over and dispose of such property if the contractor will not pay a fair price for it, and it is not the policy of the department to sell property to contractors who are known to intend to market it, or contractors who take it for speculative purposes and not for their own use."

Regulation in Bulletin No. 1

The regulation in War Department Bulletin No. 1, 1919, mentioned in the foregoing, is as follows:

II. Sale of surplus property acquired since April 6, 1917.—Section V, Bulletin No. 50, War Department, 1918, is rescinded and the following substituted therefor:

The following extracts from an act of Congress and the regulations for carrying the same into effect are published to the Army for the information and guidance of all concerned:

1. An act making appropriations for the support of the Army for the fiscal year ending June 30, 1919 (approved July 9, 1918):

* * * * * * *

SALE OF WAR SUPPLIES.—That the President be, and he hereby is, authorized, through the head of any executive department, to sell, upon such terms as the head of such department shall deem expedient, to any person, partnership, association, corporation or any other department of the Government, or to any foreign State or Government, engaged in war against any Government with which the United States is at war, any war supplies, material, and equipment, and any by-products thereof, and any building, plant, or factory acquired since April 6, 1917, including the lands upon which the plant or factory may be situated, for the production of such war supplies, materials, and equipment which, during the present emergency, may have or may hereafter be purchased, acquired, or manufactured by the United States: *Provided further,* That sales of guns and ammunition made under the authority contained in this or any other act shall be limited to sales to other departments of the Government and to foreign States or Governments engaged in war against any Government with which the United States is at war, and to members of the National Rifle Association and of other recognized associations organized in the United States for the encouragement of small-arm target practice: *Provided further,* That a detailed report shall be made to Congress on the first day of each regular session of the sales of any war supplies, material, lands, factories, or buildings, and equipment made under the authority contained in this or any other act, except sales made to any foreign State or Government engaged in war against any Government with which the United States is at war, showing the character of the articles sold, to whom sold, the price received therefor, and the purpose for which sold: *Provided,* That any moneys received by the United States as the proceeds of any such sale shall be deposited to the credit of that appropriation out of which was paid the cost to the Government of the property thus sold, and the same shall immediately become available for the purposes named in the original appropriation.

* * * * * * *

2. *a.* Bureaus of the War Department desiring to sell any war supplies, material, or equipment, or by-product thereof, or any building, plant, or factory, including land upon which such plant or factory may be situated, embraced within the provisions of the act of July 9, 1918, shall secure the approval of the Director of Sales, office of the Director of Purchase, Storage and Traffic, Purchase, Storage, and Traffic Division, General Staff, except in the Philippine and Hawaiian Departments, where the authority of the department commanders is sufficient. The foregoing does not apply to property under the jurisdiction of the American Expeditionary Forces.

b. Upon receipt of such approval from the Director of Sales, office of the Director of Purchase, Storage, and Traffic, given either specifically or by general authorization, such supplies, material, equipment, by-products, buildings, plants, or factories, including land on which plants or factories may be situated, will then be disposed of, unless otherwise authorized or directed by the Director of Sales, office of the Director of Purchase, Storage, and Traffic, for cash at auction, or to the highest bidder on sealed proposals, on due public notice, and in such market as the public interests require.

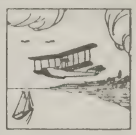
c. The proceeds of sales shall be deposited to the credit of that appropriation out of which was paid the cost to the Government of the property thus sold, and the same shall immediately become available for the purposes named in the original appropriation.

3. These regulations supersede all previous regulations, authorizations, or instructions, either special or general, heretofore issued on this subject.

4. Authorizations of sales in conformity herewith heretofore made by the Director of Purchase, Storage, and Traffic are ratified and confirmed.

[400.32, A. G. O.]

BY ORDER OF THE SECRETARY OF WAR:



PEYTON C. MARCH,
General, Chief of Staff.

OFFICIAL:

P. C. HARRIS,
The Adjutant General.

THE NEWS OF THE WEEK

Flies from N. Y. to Washington in 85 Minutes

Lieut. Frank H. Harmon, pilot, of Bolling Field, Anacostia, established the record flight from New York to Washington by aeroplane.

He lowered all previous records by more than 30 minutes in landing at Bolling Field 85 minutes after his "take-off" at Hazelhurst, N. Y. The machine used was a La Pere fighter.

New Record Flight from Washington

Captain Roy N. Francis made a record-breaking air voyage, carrying four passengers, from Washington to New York, February 18, in 2 hours and 15 minutes, which, for the 240 miles, made the speed nearly 107 miles an hour.

Better time has been made between the capital and New York by single-passenger or two-passenger ships, but this flight was the swiftest ever made by a group as large as five. Col. E. R. Hertz, commanding officer at Bolling Field, Washington, was one of the passengers and got his first view of New York from the sky.

The ship was a twin Liberty Glenn-Martin bomber, and Capt. Francis flew it to New York to the Aeronautical Show.

Kenly Commands Airmen

The War Department authorizes publication of the following General Order issued by Major General W. L. Kenly, Director of Military Aeronautics to the Officers and Enlisted Men of the Air Service:

"It seems fitting at this time to express my appreciation of the splendid work performed for the past year or more of war activities by the officers and enlisted men of the Division of Military Aeronautics. Many of you are now returning to civil pursuits with the regret that you were not among the more fortunate ones who experienced actual service overseas. To you who have labored night and day, undertaking hazardous duties in all weather, that the training of our fighting air men might continue without interruption, I express my sincere thanks for your steadfast devotion to a duty which so suddenly became apparent would involve little hope of commensurate reward. The interminable grind of performing the same hazardous duties over and over again in order that others less experienced might be fitted for the work in hand, and then to have your former students sent to the front while you 'carry on,' requires a quality of pluck and steadfast determination which the fortunate few who have never experienced such heart-rending disappointment can never understand.

"To those who serve overseas and return to this country with the satisfactory feeling of difficult duty well done, I offer my sincere congratulations for your worthy accomplishments.

"For those who met an untimely end in our service I am sure we all hope that they may receive the reward they so justly merit for the extreme sacrifice."

Navy Asks for Seaplane Bids

Washington, D. C.—The Bureau of Steam Engineering of the Navy Department has invited bids from various aircraft manufacturers for the construction of four experimental twin-motored seaplanes and the preparation of blue prints and compilation of performance data. It is anticipated that the newly designed flying boat will show considerably improved performance over the present model of large flying boat. The motive power is to consist of two 400 H.P. motors. Controls are to be provided in both cockpits of the nacelle so that the two pilots may relieve each other. Armor will protect the pilot from fire from all directions, including from astern. The total weight of the complete machine will be between 8,000 and 9,000 pounds, including about 3,000 pounds of useful load.

Toronto-Hamilton Air Line to Be Opened Soon

A passenger, freight and mail service by aeroplane is to be put into operation soon between Toronto and Hamilton, Canada, it was announced in New York by one of the syndicate who recently bought from the British Government aeroplane equipment which remained in the Dominion after the war.

This air route is to be the first of many being planned for the near future. It is a test service, in order that the operating cost of regular air lines and their general feasibility may be determined.

Army Aviator Makes Record Flight in Delivering Glenn Martin's Plane for Aero Show

New York, N. Y.—Captain Roy N. Francis, who is in charge of the Army's plans for the trans-Atlantic flight, carried four passengers in two hours and fifteen minutes, which is an average of nearly 107 miles an hour. This is the fastest time made in a plane carrying five persons for this trip.

Marjorie Stinson, sister of Katherine Stinson, is an expert pilot, and has served Uncle Sam in one of the drafting departments of the Navy Department

The ship used was a Glenn-Martin Bomber and was the first part of the thirty-odd planes to arrive for exhibition at the Aero Show.

Captain Martin has had more hours of flying than any other aviator in Government service. After directing the setting up of the plane at Madison Square Garden, Captain Francis will return to Washington in connection with his duties in arranging for the trans-Atlantic flight.

Flying Cadets Entitled to $100 Per Month to June 30

A recent decision of the Comptroller of the Treasury is to the effect that cadets who were in training for commissions in the Air Service from April 1 to June 30, 1918, should have been paid at the rate of $100 per month under the Appropriation Act of June 15, 1917.

The Director of Finance has authorized, under arrangements with the Auditor for the War Department, to settle these unpaid accounts of cadets on supplemental final statements. This holds in the case of all cadets who have been subsequently discharged or commissioned, or both. Settlement will be made in this manner not only for the difference in pay before July 1, 1918, but also for the 50 per cent. increase of pay for flying duty subsequent to that date.

The necessary forms to be filled out in getting settlement for these unpaid accounts will be furnished on application to the Director of Finance, 3202 Munitions Building, Washington, D. C.

Communications on this subject should not be addressed to the Director of Military Aeronautics, but to the above address.

Aeroplane Brake Project

An invention which the firm claim will revolutionize the aircraft industry has been patented by the Navarro Aviation Co., Ltd., of Burton-on-Trent. It is a rudder air-brake which Mr. Navarro states can be used in flight as well as on landing to slow a machine down and thus prevent accidents.

Old Manuscripts On Aeronautics On Auction

An important and probably unique collection of very early books on aeronautics, collected in England and now to be dispersed by sale at auction on the afternoons of March 10th and 11th, is on display at the Anderson Galleries, Fifty-ninth Street and Park Avenue, New York.

Though the literature of true aerostation can hardly be said to antedate Montgolfier's first successful experiment, the ancients were continually grasping after some solution of the problem, and as early as the age of Plato, Archytas of Tarentum, we are told by Aulus Gellius, the Latin historian, is said to have devised a flying dove.

The work of earliest date in this collection is therefore a copy of Aulus Gellius. Francis Bacon speculated on the subject in his Silva Sylvarum and Roger Bacon describes methods by which the object may be attained in some of his astrological books. The above and other works of a like character are included in the collection.

With the problem solved successfully in 1783-84, the true literature of flying may be said to take its inception. The present collection contains no less than fifteen works dated 1784, and as many more dated prior to 1790. One of the most interesting and important items is a large scrap book containing rare and early prints, drawings, broadsides, posters, newspapers, etc., dating from 1783, and covering a period of nearly one hundred years, some of the later items dealing with the balloon service of the French during the siege of Paris, 1870-71.

Judge K. M. Landis, his son, Capt. Reed Landis, and Mrs. Landis. Captain Landis has just returned from France, where he downed 12 Germans

Sergt. Connelly Returns an Ace

Philadelphia, Pa.—The Guaranty Trust Company announces that Sergeant James A. Connelly, of the Philadelphia office of that company, has returned after nineteen months with the French aviation corps. He is credited with having brought down fourteen Hun planes, and having taken part in sixty-five air battles. He downed seven German planes by official count and seven are reported unofficially. Connelly received the Croix de Guerre with seven palms and a gold star, and the Medaille Militaire. Sergeant Connelly was also cited in official despatches from the front in Italy as a pilot of unusual adroitness.

Control of Craft by Radio Proved

Washington.—Army and navy experts have reported favorably on the device of John Hays Hammond, Jr., for radio control of surface craft to be sent laden with explosives against enemy ships. They predict similar results with submerged craft showing above water only wireless attennæ.

Results of tests were made public in connection with the new fortifications appropriation bill, which carries $417,000 for construction of an experimental submerged boat.

Secretary Baker wrote to the House Appropriation Committee, which is considering the bill, that the joint Army and Navy Board was "convinced of the practicability of the control" of the surface craft, and added that there had also been demonstrations of the possibility of the control to a craft, completely submerged, except for an air intake pipe.

Before finally deciding on the purchase of the patents for $750,000, the board desires further experiment with the submerged craft and a change in law for the experiments is necessary to permit building so as to make success certain before purchase.

Construction of the submerged craft, which will be about 80 feet long, by 7 feet in diameter, will take two years, according to Mr. Hammond, who told the committee he has spent ten years and $400,000 on his invention.

"There is no question whatever as to the ability to control with great accuracy the torpedo or carrier, whatever kind it is," said a letter to Major-Gen. F. W. Coe, a member of the board, "so long as it is a surface vessel or has any antennae above the water, by direct radio waves, either from shore or from aeroplane.

"The board had before it also, and considered, the ability of the enemy to interfere with the control of the vessel by radio energy. Mr. Hammond's claims are that no interference can be had with the craft outside a radius of 100 to 250 yards from the source of the energy; that is, from the radio plant of a battleship, for example.

"Within such a radius a certain interference from a powerful wireless station is possible, but that interference with the apparatus only operates to keep the torpedo on a fixed course on which it may be running."

With a shore station having a height of eighty feet above sea level radio control of the craft has been demonstrated to the board up to a distance of about seven miles. But Gen. Coe said that if controlled from an aeroplane there was no limit as to distance except the propelling power of the torpedo or the boat that carried it or the aeroplane.

"A surface launch with the apparatus on it," said Gen. Coe, relating demonstrations before the board, "was controlled from both the shore and from an aeroplane, the means of control in each case being the same. The board also witnessed the dropping of depth charges from the stern of the boat while it was proceeding on any desired course."

Gen. Coe said he had run the craft "all around vessels coming into the harbor at will," and at close ranges there would be no difficulty in ramming a vessel from shore.

Mr. Hammond said an aviator after four hours training on control was able from a height of 9,000 feet and a distance of six or seven miles to exercise absolute control over the high speed boat.

"World's Greatest Flying Circus" at Rockwell Field to be an Annual Event

Rockwell Field, in its "World's Greatest Flying Circus," held at the field on North Island in San Diego Bay on February 2, instituted what promises to be an annual ocurrence that will supplant in popular favor the time-honored saw-dust ring, annual football games, Mardigras, and every other fete that makes its yearly round.

By permission of Lieut. Col. Harvey Burwell, Commanding Officer, the entire field and its equipment were turned over to the use of the circus. As the Rockwell Field *Weekly Flight* puts it: "Hundreds of intrepid aviators, in the roles of circus men, risked their lives in the performance of the most spectacular feats known to the flying game; the 'big top' was limited only to the cloud-flecked sky; huge battle planes were the horses ridden; and the god of chance was the ringmaster. A capable director he proved, too, for not an accident happened to mar the entire flying program." There were sham battles and all the strategic moves of aerial warfare, both in single encounter, pursuit and formation. Parachutes were dropped from aeroplanes, and a captive observation balloon, brought from the Arcadia Balloon School, demonstrated parachute drops from the basket of its big "cigar."

The concessions or side-shows of the circus were novel and aeronautical. A shooting gallery had small aeroplanes for targets and a sign read, "Get five planes and become an ace." Near by was a tent where one could get "flying instructions" for a quarter of a dollar. Over at another booth a sign read, "Are you physically fit to fly 30,000 feet in the air, with both feet on the ground? Come in and try." In another booth many talked over the new wireless telephone. These are but samples of the many. Old-fashioned Southern barbecued meats, cooked over wood coals, were served in some of the booths, and in others fake cabaret stars danced and sang.

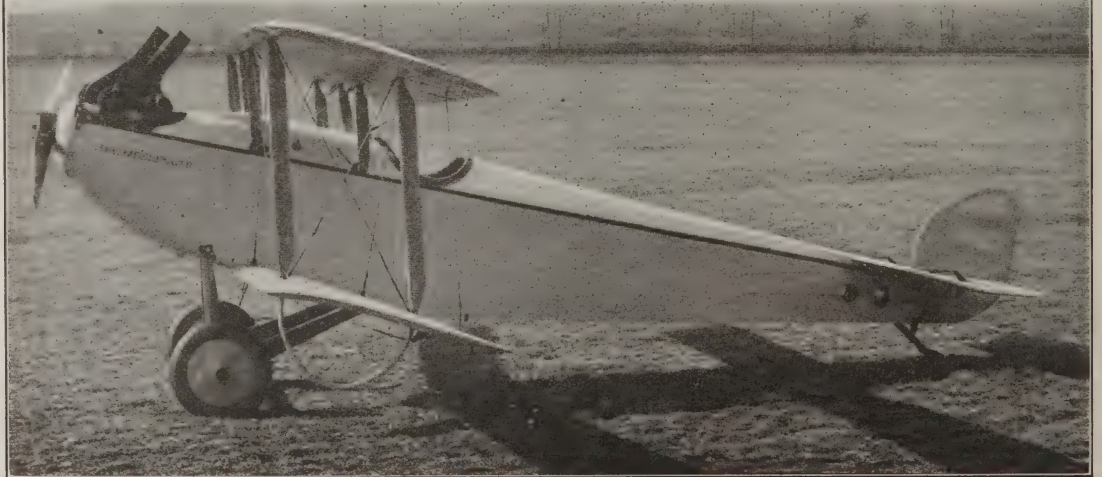
The crowd came by train and by motor, and, despite threatening weather, was one of the largest San Diego has seen. For most, it was their first close-up view of Rockwell Field. All were amazed at the extent of the improvements, at the buildings, the paved streets, the splendid flying field, the equipment, and the ability and discipline of the men. It was the first time in more than twenty months that the general public had been permitted to make an inspection of the aeronautical shops. Each department of the flying school gave, as part of the day's entertainment, lectures on its own work. Experts explained the various types of motors, guns and planes; and every piece of machinery was, besides, well placarded to show its particular use.

The climax of the day, however, was not in the circus itself. It was instead a replica of what has taken place many times on the battle front in France, with full military ceremony. This was the presentation of the Distinguished Service Cross to Major Carl Spatz and of the Croix de Guerre to Major Kenneth Marr. The presentation was made by Colonel H. H. Arnold, District Supervisor of the Western District of the D. M. A. The Quartermaster General had been directed to have the cross for Major Spatz sent to the Commanding Officer of the field, and the Secretary of War had directed that upon its receipt it be presented with appropriate ceremonies. The citation of Major Spatz for extraordinary heroism during the St. Mihiel offensive, September 26, 1918, has already been published. This was read at the presentation, as was also an order from the headquarters of the French armies of the east citing Major Kenneth Marr for the Croix de Guerre and describing him as an "excellent squadron commander of a legendary bravery, who has been a beautiful example for his entire unit."

A subsequent feature of the program was a presentation of medals to the Boy Scouts of Coronado.

Rockwell Field lays not a little of the credit for the success of the day to the work of the nine bands that played continuously. These bands were from the Balboa Park Naval Training Station, Camp Kearny (three bands), Rockwell Field, Naval Air Station, Fort Rosecrans, and the Section Naval Base.

Among the distinguished visitors at the circus as guests of Lieut. Col. Burwell were Major Gen. Guy Carleton, commanding Camp Kearny; Rear Admiral William Fullam, commander of the reserve force, Pacific fleet; Glenn Martin, vice-president of the Wright-Martin Aircraft Corporation; Col. Henry H. Arnold; Lieut. Commander E. W. Spencer, commander of the naval air school, North Island; Brig. General W. C. Short; Colonel Guy Rowe; Colonel J. R. Pourie, commander of the seacoast defenses of San Diego; Captain Arthur McArthur, commander of the naval training camp, Balboa Park. Most of these officers were accompanied by their wives; and Mrs. Newton Baker, wife of the Secretary of War, and Mrs. William Kenly, wife of the Director of Military Aeronautics, were also guests of the commander.



The net profit of the circus was set down as $4,742. This is to be devoted to the Rockwell Field Athletic Fund and to the expenses of the great international exhibition, which it is planned to give at North Island, November 11, 1919, the date set for the annual event.

De Palma Breaks Records With Aero Engine Packard Car

On the beach at Daytona, Florida, Ralph De Palma, driving a Packard special aviation twin six, of 905 cubic inches piston displacement, has strengthened his position as the "Ace" of automobile speed demons.

Under the official auspices of the Automobile Association of America, De Palma thundered off the speediest twenty miles that have ever been covered in an automobile, and brought back the world's speed honors to an American car, whereas most of the former records up to twenty miles had been held by cars of German make.

The new speed marks set up by De Palma are as follows: One mile, 24.02 seconds; two miles, 49.54 seconds; three miles, 1 minute 15.04 seconds; four miles, 1 minute 39.77 seconds; five miles, 2 minutes 4.58 seconds; ten miles, 4 minutes 9.3 seconds; fifteen miles, 6 minutes 48.75 seconds; twenty miles, 8 minutes 54.2 seconds.

The Dayton-Wright "Messenger" Biplane. It has a wing spread of 18 feet 5 inches, weighs 476 pounds net, 636 gross, has a maximum speed of 78 miles per hour, minimum 40 miles, and is equipped with a 37 horsepower motor

Want Roosevelt Cemetery in France

To acquire Belleau Wood from France by purchase or otherwise and convert it into an American national cemetery in memory of Theodore Roosevelt is a proposal that has been laid before the Roosevelt Permanent Memorial National Committee, according to an announcement made by the committee on February 23.

The proposal, first made three days after Col. Roosevelt's death by Miss Agnes Shufeldt, of Johnson City, N. Y., has the idorsement of many of the friends of the late President, including Lawrence F. Abbott, Richard Washburn Child, Arthur F. Cosby, Col. John C. Greenway, John Mitchell, Samuel Parsons, W. F. Purdy and Cushing Stetson.

The suggestion which comes to the committee is that the Belleau Wood, already called by the French "the Wood of the Marines," be made the final resting place of the bodies of the American dead whose families prefer to leave them upon French soil. The grave of Quentin Roosevelt is close to the Belleau Wood, and it is thought that it would be included in the proposed cemetery.

Italy Honors 2 U. S. Airmen

New York, N. Y.—The memory of two brave American aviators who met death in aerial combat on the Italian front was honored February 23 in the City Hall when their fathers received medals awarded by Italy. The father of Lieut. Coleman De Witt Tenafly received a gold medal, awarded by the King, and the father of Lieut. James Bahl received a silver medal, awarded by General Diaz, the Italian Military Chief. Major-General Guglielmotti, Military Attache of the Italian Embassy, represented the donors. Major F. H. La Guardia and many other aviators attended the ceremony.

Lieuts. Tenafly and Bahl were killed October 27 last when their Caproni plane was attacked by five enemy machines. They put up a desperate resistance and brought down two of the German machines before their own machine was shot down.

First Aviation Attache

Great Britain has taken a new departure in the composition of her diplomatic group in Washington, being the first nation to appoint an Aviation Attache. The first man to act in that capacity will be Brigadier General Lionel E. O. Charlton, now on the way to his post with Earl Reading, who is returning from London.

Military aviation thus takes its place as a separate and distinct service and shares the importance hitherto accorded only to the army and the navy. The appointment of such a functionary for service in Washington is a recognition of the eminent place which the United States occupies in the development of the aeroplane and is evidence of the expectation of further and important advances.

General Charlton, the first man chosen for the post, is a distinguished soldier as well as an authority on aviation, he having been decorated by his own government and also by that of France. In the war he was a squadron commander in the Royal Flying Corps.

Aeroplane to Make 300 Miles an Hour

Paris, Feb. 23.—An aeroplane with a speed of from 200 to 300 miles an hour, which will bring America within a short day's journey of Europe, is the prospect held out by the invention of a French engineer, Auguste Rateau, acording to the *Matin*. The invention of M. Rateau was one of the surprises in store for the Germans which were about to be revealed when fighting ceased.

At the present time without the invention the higher an aeroplane mounts the less power does its engine develop on account of the rarefying of the air. The loss at 15,000 feet, for instance, is 50 per cent.

M. Rateau's device, the paper says, is very simple. It consists of an arrangement by which the exhaust from the engine works a small turbine which compresses the air drawn into the engine to normal pressure so that the engine develops full power no matter what the altitude. As the resistance of an aeroplane decreases enormously at high altitudes, the *Matin* adds, it follows that the higher a machine fitted with the new device mounts the greater will be its speed. This fact, it is declared, was demonstrated by the famous German long-range gun.

It has been found that a heavy day bombing machine whose speed at 15,000 feet ordinarily did not exceed 80 miles an hour made 140 miles an hour when fitted with M. Rateau's invention.

Aeroplanes Used in France for Milk Distribution

Communication from France on February 21 to Mrs. Warren McConihe, president of the New York Committee of Free Milk for France, stated that the crippled condition of the French railroads had made it necessary to distribute the milk throughout Northern France by aeroplane. It is the first time that aircraft have been used in the extension of relief in France, although similar methods were resorted to many months ago in Italy.

Aeroplane in Agriculture

In connection with scouting and other survey work in Texas the United States Department of Agriculture is putting the aeroplane to its first practical application in agriculture. A try-out of this method of survey was made last year along the Trinity River and resulted in the discovery of several outlaw cotton fields in heavy timber, which had previously escaped detection. This year the aeroplane is to be used more extensively. It has been found a valuable aid in pink bollworm work, as it makes possible the easy mapping, by means of photographs, of the quarantined territory, and facilitates the inspection work in forested areas, especially in such long stretches of country as the valley of the Rio Grande and its tributaries.

Admiral Sims Expects Trans-Atlantic Flight Next Summer

Washington, D. C.—Rigid airships in the future will comprise a specific element of the fleet of every first-class naval power, Vice-Admiral Sims said in a wireless message made public February 23 by the Navy Department. The admiral said that observance of the naval lessons of the war had thoroughly convinced him of the importance of these machines and he recommended that the United States lose no time in developing them.

Secretary Daniels included the message in a letter sent to Senator Swanson, chairman of the Senate Naval Committee, expressing the thanks of the department for the favorable report of its recommendation that $36,000,000 be appropriated for the development and construction of rigid airships.

England is making rapid strides in the new line of military aeronautics, Admiral Sims said, having already built airshps 695 feet long, with a displacement of 2,700,000 cubic feet, a maximum speed of 59 knots and cruising period of more than 200 hours.

"Following the signing of the armistice," the admiral added, "this programme was so modified as to provide that new construction and development work be pushed even more actively than during the war."

Admiral Sims confirmed printed reports that the British Admiralty the coming summer intends a flight to the United States and return with one of these new ships and declared that the chances are better than fair that it will be successful.

"Without hesitation," Admiral Sims said, "I can recommend on strong military grounds that two more airships of the latest type be started in the United States and that these be followed by at least two more of an improved type for helium gas. This should involve an adequate building and repair base and an operating base to be located later."

Flyers Reach Mobile Enroute to Houston

Mobile, Ala.—The Handley Page aeroplane which is making its first trip from Elizabeth, N. J., to Ellington Field, Houston, Texas, carrying eleven passengers, arrived in Mobile at 12.30 P.M., Sunday, February 23.

The aeroplane left Americus, Ga., Sunday morning at 9 o'clock and made the trip of 252 miles in 3½ hours.

The machine is operated by Lieut. George M. Palmer as pilot, assisted by George L. Bradford. The officers expect to complete the trip by Wednesday. They will leave here at 9 o'clock Monday morning for New Orleans.

Aviators' Clubhouse National Memorial

A club house that is to be a memorial to the American aviators who lost their lives in the great war is to be erected in Washington by the National Aeronautic Committee, No. 289 Madison Avenue, New York, of which Mrs. Charles A. Van Rensselaer is president. The club house will be the home of the Army and Navy Air Service Association, until a few days ago the Air Service Clubs Association.

Mrs. Van Rensselaer made her offer at the meeting at which the association changed its name and admitted many fliers to membership. The association was an army project, having grown out of a plan evolved by Major Maxwell Kirby, who was commandant of Gerstner Field, Lake Charles, La., when Major John Purroy Mitchel lost his life. Now the navy is represented on its Board of Control by Commander John H. Towers, U. S. N., a pioneer airman.

The committee of which Mrs. Van Rensselaer is the head has been active in behalf of the comfort of aviators since the United States entered the war. The first work to which it devoted its energies was the establishment of a balloon training school at Stapleton, S. I. Then it took up the supplying of athletic sports equipment, and by the time the armistice was signed had outfitted 207 overseas squadrons and had sent complete supplies to 22 training fields in this country at costs ranging from $500 to $2,000.

This recognition of the need of athletic sports for men in so hazardous an arm of the service as aviation won the committee the cordial indorsement of officials, among the most approving being Major General W. L. Kenly, Director of Military Aeronautics.

Last fall the committee gave at Belmont Park an Aviation Carnival which was the most spectacular thing of the sort ever seen in the East. In the announcement of the project made by the association it is said:

"One of the principal functions of the association is to bring air service officers closer together for the good of the air service and aeronautics in general. The club house will be for officers of the air service of both the army and navy, either active or discharged, when the best things they have learned in the service of their country can be encouraged and perpetuated."

Board to Review Flying Rewards

Major Gen. W. L. Kenly, Director of Military Aeronautics, has appointed a board of officers to pass upon the qualifications and merits of flying officers who have distinguished themselves in action. The board will review all the records with a view to awarding flying officers such ratings as their achievements warrant. These ratings will carry an increase in flying pay. This action is in recognition of the fact that the list of pilots credited with destroying five or more aeroplanes is incomplete and that officers on details of ten, requiring a greater amount of skill in fighting, deserve recognition in the way of higher rating and appropriate rewards.

A line-up of German aeroplanes turned over to the French under the terms of the armistice

The AIRCRAFT TRADE REVIEW

A. E. J.

Wright-Martin Turns Out Combination Liberty-Hispano-Suiza

New Brunswick, Feb. 10.—About 2,000 workmen are still employed by the Wright-Martin Aircraft Corporation on a Government aeroplane engine contract, which will be completed in about a month. It has developed, according to *Automotive Industries*, an aeroplane motor combination of Liberty-Hispano-Suiza, and has a four- and six-cylinder engine completed.

Frank Mossberg Joins Rice Leaders

Attleboro, Mass., Feb. 10.—The Frank Mossberg Co. has become a member of the Rice Leaders of the World Association.

Aeroplane Show for Chicago

Chicago, Feb. 11.—Chicago will hold its first aeroplane show at the Coliseum, March 29 to April 5. Louis Disbrow is the promoter. He and George W. Browne, Wisconsin distributer for Willys-Overland and distributer in Wisconsin and Illinois for Curtiss, have formed the International Airplane Exposition Co., and may put on similar shows elsewhere. Four Curtiss planes are promised for exhibition. Bart J. Ruddle of Milwaukee will manage the show.

Johns-Manville Co. Give 20% Bonus to Employees

In appreciation of the good work of its employees during the strenuous war period, the H. W. Johns-Manville Co. has decided to distribute among all employees who have been in their employ for the full year of 1918, excepting officers of the company, an extra compensation of 20 per cent. on the salaries paid them during the year. This compensation will entail an expenditure of more than $1,000,000.

Motor-Driven Valve Grinder On Market

A new tool, an electric motor driven valve grinder with an oscillating spindle and designed to supplant the laborious hand grinding, has been put on the market. The device is controlled by a trigger similar to the trigger of a revolver. The spindle oscillates with a long, steady sweep similar to the movement obtained in grinding by hand, but many times more rapidly. A 1/6 H.P. motor is used, which is air cooled. It operates on standard power circuits either alternating current with range 25 to 60 cycles or direct current, being made for circuits of 110 volts, 220 volts, and 32 volts.

The motor and gearing with reciprocating mechanism are completely enclosed in an aluminum housing, the gearing and oscillating movement being separated from the motor compartment and packed in grease. The grinding spindle runs in a ball thrust bearing. Armature shaft runs on Norma ball bearings, and gears are mounted on shafts ground to size supported at both ends in long phosphor bronze bushings. Bits are provided to make the tool adaptable to various types of valves.

Personal Pars

R. G. Ames has joined the Black & Decker organization as branch manager of the Chicago office.

Mr. Carroll M. Aument, formerly one of the engineers of the Wright-Martin Aircraft Corporation, has resigned his position and opened a consulting, designing and sales engineering office under the name of Aument & Gillespie, at 87 Nassau Street, New York City.

Lieutenant-Colonel Grayson M. P. Murphy, senior vice-president of the Guaranty Trust Company, who was in charge of the American Aviation Forces in London, has returned to the United States and is back at his desk.

J. J. Tobias is in charge of the new Detroit branch of the Moto Meter Co., Inc., 2019 Dime Bank Building.

C. L. Diers, formerly in charge of the Indianapolis branch of the Goodrich Tire & Rubber Co., Akron, is now in charge of the European division, covering Europe, Asiatic Russia and the northern coast of Africa.

F. H. McFarlin has joined the sales department of the Erie Specialty Co., Erie.

Junior Plattsburg to Have Aviation Ground School

A department of aeronautics has been added to the curriculum of the next Junior Plattsburg, according to an announcement made by E. C. O'Brien, managing director. The course will be similar to that offered at government ground schools, including instruction in the theory of flying, elementary aerodynamics, motor mechanics and structural design. To this will be added military aeronautics, including aerial reconnaissance, aerial photography, map-making, elementary aerial navigation, aerial communication and the theory of aerial gunnery. The courses will be given by experienced aviators and the equipment will consist of 5 JN-4D Curtiss planes, in which the majority of American aviators were trained, and one MF flying boat. A Curtiss OXX motor will be used for laboratory work. Upon completion of the course each cadet, upon authorization by his parents, will be given a practice flight.

Johns-Manville Employees Receive Extra Compensation

Many progressive business organizations have adopted one or another form of profit-sharing plan for employees. Few, however, have shown so great liberality in this respect as the H. W. Johns-Manville Company, miners and manufacturers of asbestos, and allied products, who will distribute to all salaried employees—men and women—from heads of branches and departments to office boys, who have been in continuous service for the full calendar year nineteen eighteen, an extra compensation of 20 per cent on the salaries paid them during 1918.

It has been the custom of the H. W. Johns-Manville Company for some years past to recognize the faithful service of their big business family in this substantial way.

During the past two years especially, the members of this organization, in common with many others, have been working under an exceptional strain, owing to the depletion of their ranks through enlistment and the high pressure of war production.

In appreciation of this fact, the H. W. Johns-Manville Company has at the end of each war-year, 1917 and 1918, set the mark even higher than before—a full 20 per cent of the year's salary.

This extra compensation for 1918 will cost the company approximately $1,000,000.

Represents American Accessory Manufacturers in England

Mr. H. K. Lakin, of the firm of Stanley J. Watson, of London, England, agents for the Eisemann Magneto Co., the Federal Bearings Co., and others, is visiting the United States, and will be located in Room 714, 220 Broadway. He is negotiating with various firms who have been seeking live representation in England for the British agency for American products, and is desirous of extending his connection with the American industry by adding more accessory manufacturers to his clientele.

Honorably Discharged

America's leading "Ace," Captain Edward V. Rickenbacker, A. S. A., who reported at the O. D. M. A., February 10, 1919, was honorably discharged February 13.

The following officers of the Air Service were discharged on the dates noted:

February 10, 1919: Captains William N. Neidig, Clarence G. Spencer, Laurence E. Rubel, Samuel P. Burnam, Daniel C. McCoy, Robert R. McMath, First Lieuts. George H. Pfau, Robert J. Love.

February 13, 1919: Lieut. Col. John A. Drexel, First Lieut. Thomas F. Ward, Second Lieut. Aaron Prussian.

February 14, 1919: Captains David R. Wheeler, Maury Hill; Second Lieuts. Harold Palmer, Edwin S. Ladley, Wallace J. Frost.

February 15, 1919: Lieut. Col. Thomas G. Gallagher, Major Walter G. Rogers, Captains Michael J. Phillips, John McQuerney, Otis S. Van De Mark, Charles M. Neubauer; First Lieuts. William G. Garrett, Edward F. Dean; Second Lieuts. Harry A. Van Horn, John M. Saunders; First Lieut. Lawrence W. Kinnear.

February 17, 1919: Major Charles S. Jackson, Second Lieuts. Thomas H. Owen, William T. Ashby.

February 18, 1919: Captains Leonard C. Hammond, Claude O. Van Valer, Second Lieut. Robert G. Elbert.

New R. M. A.'s

The following officers have been rated Reserve Military Aviators: Second Lieuts. James B. D. Palmer, A. S. A., and Harvey Ashfield, A. S. A., to date from January 30, 1919; and Second Lieut. Walter William Roop, A. S. A., to date from January 18, 1919.

Soon to Return

The following organizations have been assigned to early convoy:

Eighth Aero Squadron.

Photographic Section, Air Service, No. 17.

Photographic Section, Air Service, No. 23.

Lieut. Col. Jacob E. Fickel, J. M. A., A. S. A., Captain George Washington Price, A. S. A., and Captain Louis Montford, A. S. A., have been appointed members of the Board of Contract Review of the Division of Military Aeronautics, created September 23, 1918, vice Lieut. Col. Harold Benington, A. S. A., Captain Otis S. Van De Mark, A. S. A., and Captain Lewis B. Ticknor, A. S. A., relieved.

Lieut. Col. Herbert A. Dargue, M. A., A. S. A., was recently ordered to proceed from Washington, D. C., to Post Field, Fort Sill, Oklahoma; thence to Air Service School for Radio Operators, Penn Field, Austin, Texas; thence to School of Military Aeronautics, University of Texas, Austin, Texas, in connection with an investigation of the facilities existing at Penn Field, for the establishment of a permanent radio school.

A Board of Officers consisting of the following personnel, Col. William N. Hensley, Jr., J. M. A., A. S. A.; Col. James Prentice, J. M. Aer., A. S. A.; Maj. Frank M. Kennedy, J. M. Aer., A. S. A., Commanding Officer, Langley Field, Captain John McInerney, A. S. A., met at Langley Field, Hampton, Virginia, for the purpose of reporting upon the location of a dirigible hangar and making recommendations as to what lighter-than-air activities may be advantageously carried on at that place together with construction required therefor. Col. Arthur L. Fuller, in charge of Lighter-than-Air Training, and Acting Chief of the Training Section, met with the Board at Langley Field.

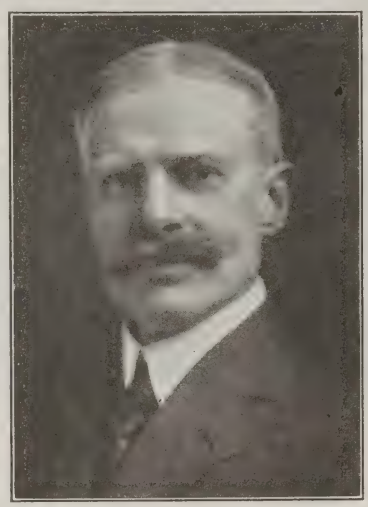
Captain Roy N. Francis, A. S. A., who was ordered to proceed by aeroplane from Washington, D. C., to Hazelhurst Field, Mineola, Long Island, New York, piloting a Martin bombing machine, made the trip successfully on February in 2 hours and 30 minutes.

Aviators Cited for Promotion

The following twenty American flying officers distinguished themselves overseas and have been recommended for advanced flying ratings, carrying extra pay:

Lieut. Col. William Thaw, Pittsburgh; Major David McK. Peterson, Honesdale, Pa.; Capt. Ed. V. Rickenbacker, Columbus, Ohio; Capt. Reed G. Landis, Chicago; Capt. Douglas Campbell, Mount Hamilton, Cal.; Capt. Edgar G. Tobin, San Antonio, Tex.; Lieut. Louis G. Bernheimer, New York; Lieut. William P. Erwin, Chicago; Lieut. Robert F. Raymond, Newton Center, Mass.; Lieut. Donald B. Warner, Swanstoc, Mass.; Lieut. James A. Keating, Chicago; Lieut. Paul W. Drew, Philadelphia; Second Lieut. Earl W. Porter, Chicago; and the following deceased officers: Lieut. Fred Norton, Columbus, Ohio; Lieut. Edward Orr, Chicago; Lieut. Merton Campbell, Wakeman, Ohio; Lieut. Lloyd A. Hamilton, Burlington, Vt.; Lieut. John O. Donaldson, Washington, D. C.; Second Lieut. Frank B. Bellows, Williamette, Ill., and Second Lieut. Roger Hitchcock, Mount Carmel, Ill.

A NEW PRINCIPLE IN CARBURETION



CONSIDERABLE interest has been shown in the novel design of the Brown Carburetor, which has embodied therein a new principle in carburetors. This device is the invention of one of the older automobile engineers, George M. Brown, of New York.

The absence of all cams, springs, dashpots, and the moving parts is noteworthy, also the tendency to get away from the venturi tube idea, the compactness and neatness of design attracts the eye of the engineer desiring to clean up his power plant.

The correct ratio of air and fuel is maintained at all speeds without the use of adjustments of either fuel or air, this is accomplished automatically for either warm or cold weather operation.

Figure 1 shows a sectional view of the top opening type. "A" represents the only air intake (there being no auxiliary air intakes) ;"B" is an air baffle plate which has openings in the sides with an area equal to the area of the air intake. The lowest end of this plate is curved in toward the wall of the mixing chamber "C," and has a narrow opening at its lower end. The mixing chamber "C" is spherical in shape and has a fuel nozzle "D" at its lowest point. The height of this fuel nozzle is set at the factory. "E" is the outlet baffle plate which also has openings of a predetermined shape and size at either side; "F" is the throttle valve, and "G" is a choke valve. The gasoline bowl "H" is directly under the mixing chamber "C". "I" is a metal float which controls the depth of the fuel in the bowl and is connected to a shut-off valve "J" through the ferculum arm "K". The shut-off valve "J" is threaded at its middle portion and the fuel can be adjusted by means of the nut "L". "M" is the fuel duct and the fuel enters same from the bowl through the opening "N".

In operation, air is admitted through the air intake and passes through the side openings of the baffle plate into the mixing chamber and coming in contact with the curved walls of the mixing chamber is caused to travel in a circular direction. The speed of this air is, of course, controlled by the throttle opening and the motor suction at low speed. The action of the air in entering the mixing chamber is such as to draw the proper amount of fuel through the fuel nozzle. This fuel is immediately atomized by the revolving air, the tendency of the incoming air being to create as low suction at the lowest speeds over the fuel nozzle owing to the fact that the greatest air momentum is at these speeds toward the outside walls of the mixing chamber. As the motor speed increases by opening the throttle, the increased volume of air passing through the mixing chamber causes more suction over the fuel nozzle as the increasing volume of air tends to spread out in its path toward the centre of the mixing chamber.

George M. Brown, Inventor of the Brown Carburetor

The outlet baffle openings, also, tend to control the air in mixing chamber by the removal of the gas mixture much the same way that the air is controlled by the intake baffle plate. The reason for this is to balance the direction of the air in the mixing chamber. There is a set idling jet for motor idling; this being a nozzle with fixed opening.

Laboratory and road tests have covered all conditions of motor operation, and the automatic action is uniform under all conditions.

Lack of space prevents the publishing at this time performance curves, but we present a memo from a few tests.

A car equipped with a six-cylinder motor 3⅜ bore and 4½ stroke, weighing 3,475 pounds with driver and observer over a fifty mile course, temperature 34° F. made an average speed of 25 miles per hour, consumed gasoline (63 test) at the rate of .233 pounds of fuel per mile, or 22.3 miles per gallon.

Block test with same motor consumed .512 pounds fuel per brake horse-power per hour at 78% full load.

Tests made for fuel leakage to oil reservoir showed that in 78 hours test on road, there was no perceptible change in the oil except that which would occur through the re-use of the oil.

Carbon residue was almost totally absent; especially was this true on top of pistons and heads.

The carburetors are now being manufactured in ¾, 1, 1¼, 1½ and 2 inch sizes by the Brown Carburetor Corporation, with Engineering Offices at 1790 Broadway, New York City.

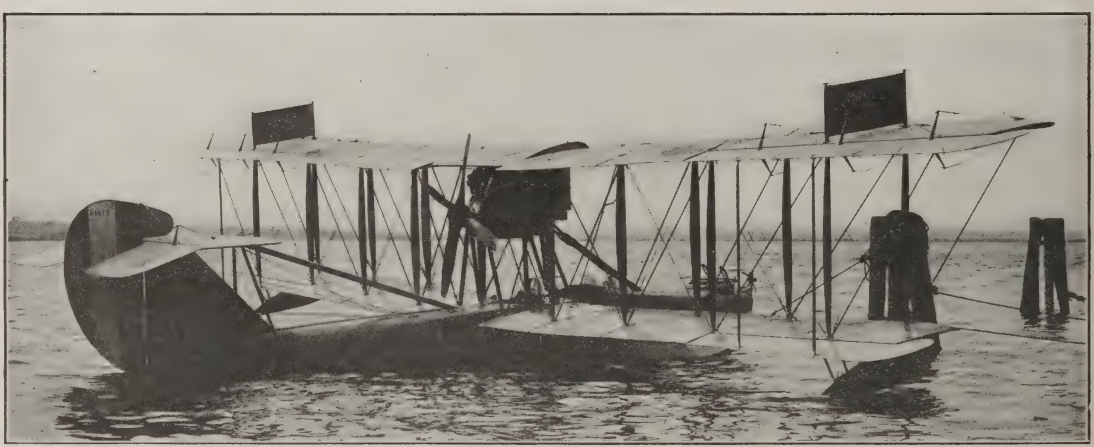
GALLAUDET D-4 BOMBER

The Gallaudet Bomber has a Liberty Engine of 400 H.P. driving a four-bladed pusher propeller. The machine is a two-seater with pilot and observer placed well forward. Fuselage finely streamlined and the placing of the lower wings below the fuselage brings the center of thrust in a very desirable location. A maximum speed of 126 M.P.H. and a climb of 2,100 feet in 2 minutes was recorded in an official test flight

CURTISS MODEL M. F. FLYING BOAT

The Navy Department has employed a great number of the M. F. Boats for coastal training work. Machine is well suited for marine sportsmen for it is comparatively small and is easily handled. The boat is provided with either a Curtiss OX 5 100 H.P. engine or the new Kirkham K-6 150 H.P. six-cylinder vertical engine. The M. F. Boat is an improvement in design over the Curtiss F Boat which found so much favor before the war stopped civilian flying



The Curtiss H-16 Flying Boat. The H-16 has two 400 H.P. Liberty Engines. Two guns and a gunner are carried at the bow, and behind them, in an inclosed cabin are the two pilots. In the after part of the boat, two guns are arranged to be fired through windows in either side of the hull. Such machines as these were used in large numbers for submarine spotting and long range coast patrol work

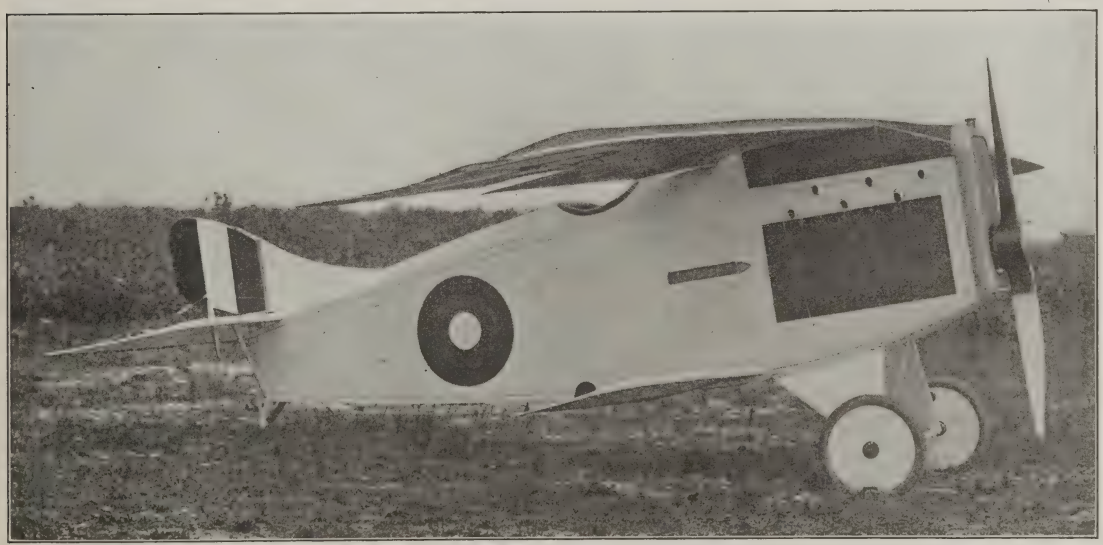
The Glenn L. Martin biplane, equipped with two Liberty motors, which has made a number of extraordinary records in the past three months

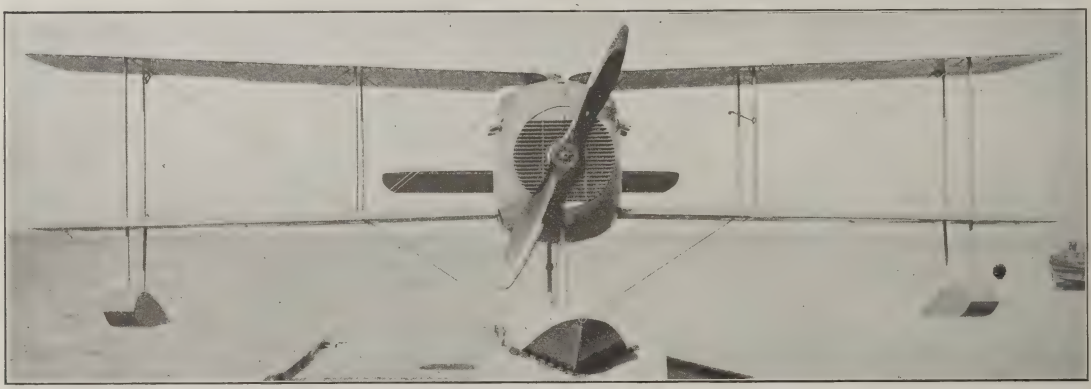


The Model H. S. 2 L. Flying Boat, constructed by the Standard Aircraft Corporation

The Bellanca Biplane, showing the neat appearance of the warping wings and streamline body

The Glenn L. Martin twin Liberty engined bomber that flew from Pittsburgh to Washington, a distance of 175 miles in one hour and fifteen minutes

Christmas "Bullet" strutless and wireless biplane which makes a speed of 170 miles an hour with a 6 cylinder Liberty Motor



The Dayton-Wright "Sedan" carries two passengers and a pilot. It is completely enclosed and has a body with four windows on either side, has electric ceiling lights, upholstered swivel chairs, a card or dining table and rugs on the floor. It was designed under the direction of President Harold Talbott of tne Dayton-Wright Company

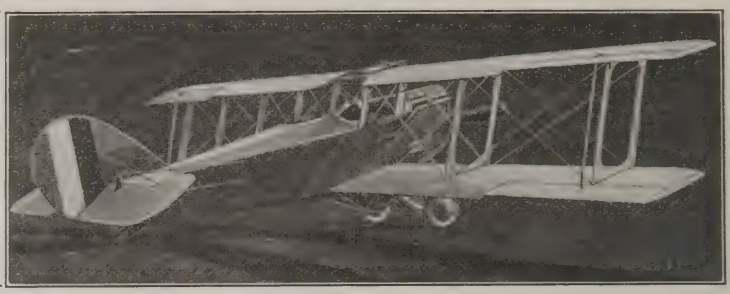
The Dayton-Wright "Honeymoon Express." It has two upholstered sea built-in mahogany vanity and lunch boxes, and bevel plate mirrors. It holds two passengers and pilot. It is painted in cream and black and is equipped with a Liberty Twelve. The machine has a maximum speed of 115 miles per hour and minimum of 53

Curtiss Model H-A Mail Machine. Streamline has been carried out to a very effective degree on the Curtiss Model H-A Mail Machine. The fuselage is exceptionally deep, wings being attached directly to the fuselage and a single pair of struts used at either side. A Kirkham model K-12 engine is used, connected to a four bladed propeller with high pitch. The photograph shows the neat way in which exterior control wires have been eliminated

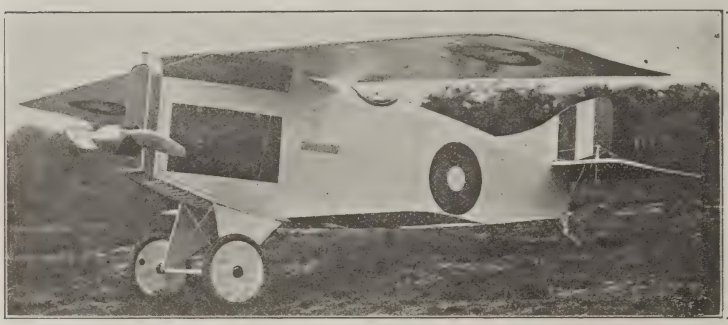
The Curtiss Model H-A Hydro. An unusual feature in this machine is the single pair of struts from the pontoon to the fuselage, the deep body and the elimination of struts between the wings and body. The upper plane has the customary positive dihedral but the lower planes slope downward in a negative or reversed dihedral. The Hydro resembles in many respects the H-A Land Machine but two sets of struts are used on the Hydro because of the greater span

Sundstedt-Hannevig Seaplane. This seaplane was designed for the Trans-Atlantic flight. It is provided with two Hall-Scott engines with propellers in pusher position. The cabin, accommodating four persons, contains the appointments usually found in a limousine, including cushioned seats, electric ceiling light, glass windows, and wind shield. The instrument dashboard contains a map case which conveniently holds the charts which will be used in attempting the trans-Atlantic flight.

The Curtiss Model K triplane equipped with the Curtiss K-12 engine



Three-quarter aero of the Curtiss Model K triplane



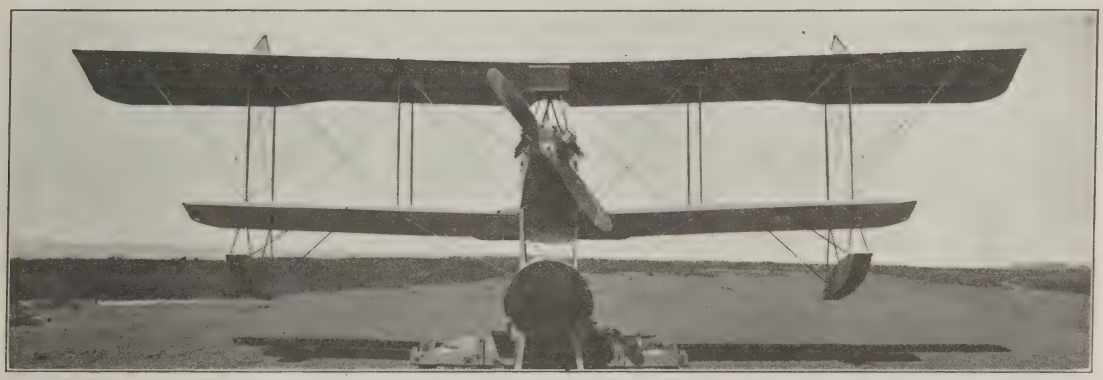
The Standard ME-1 defense Scout, equipped with 80 H.P. Le Rhone engine

LE PERE FIGHTER

The Le Pere has a span of 39 feet, and overall length of 25 feet and a height of 10 feet. Ground speed 136 M.P.H. A "Liberty 12" 400 H.P. engine is used. The fuselage is built up of Veneer

CHRISTMAS "BULLET"

With a Liberty "6"—185 H.P. engine, the "Bullet" has attained a speed of 175 M.P.H. The upper plane has a span of 20 ft. and no bracing is used to keep them rigged. Minimum speed 50 to 60 M.P.H. Cruising radius 550 miles



The "Standard" Type E4 Mail Plane, which has a capacity for carrying 180 pounds of mail. With an Hispano-Suiza 150 H.P. engine the machine makes a speed of 100 M.P.H.

The Curtiss NC-1 returning from a trip

The J. V. Martin Tractor. One of the very original machines developed in this country by Captain James V. Martin for the Signal Corps. A single Liberty "12" engine drives two four-bladed tractor screws by means of bevel gears. This machine has the Martin automatic wing-end ailerons, K-bar interplane struts and other unusual mechanical constructional features

FRONT VIEW OF THE 100 H.P. AEROMARINE NAVY TRAINING SEAPLANE

The Aeromarine Navy Training Seaplane. It is equipped with a Curtiss OX 100 horse-power engine or the new Aeromarine 130 horse-power engine. This seaplane is of the single float type, a development of the Aeromarine twin float Seaplane which has been used extensively by the Navy Department. With the single float the machine is easy to manoeuver on the water

The Aeromarine Model 40 T Flying Boat is provided with a 100 horse-power Curtiss OX engine. This machine has been designed to answer requirements of the sportsman. The Aeromarine 130 horse-power Type L engine is supplied when desired. Span of Upper Plane 48 feet; Chord, 75 inches; gap, 78 inches; total weight 1,925 pounds; weight fully loaded, 2,485 pounds. The wing floats have a buoyancy of 264 pounds. 35 gallons of gasoline are carried

THE MANUFACTURE OF VENEER AND PLYWOOD

By B. C. BOULTON, B. S., A. E.

THE development, during the past year, of plywood in its application to aeroplane construction has been greater than that of any other material. Previous to 1918 plywood had been used more or less successfully in fuselage work, and in a somewhat crude way in rib construction. At that time but little definite information was available regarding its properties, design, or the method of applying it. Since then a great deal of experimentation has been carried on by several of the leading manufacturers of plywood and by the U. S. Government, both at McCook Field, Dayton, Ohio, and at the Forest Products Laboratory, Madison, Wis. As a result of their work the efficiency of this material, especially in fuselage and rib construction, has increased more than 100 per cent. and several new applications for it have been developed. The processes used in the manufacture of veneer and plywood are therefore of unusual interest to the aircraft designer and builder.

In the veneer industry there are two distinct manufacturing operations—the cutting of the log into thin sheets, known as veneer, and the building up of this veneer into plywood. The larger plants, as a rule, carry on both these operations simultaneously, but at the present time there are many factories devoted wholly to the cutting of veneer, while others specialize in the manufacture of plywood. Woods which are most used for veneer are birch, poplar, basswood, spruce, Spanish cedar, maple, mahogany, walnut, gum, ash and oak. For aeroplane work different species are often used in combination in plywood, depending on the properties that are desired.

As the logs are unloaded at the veneer mill they are separated according to their variety. Although it may often be impossible to cut up the logs immediately, an important principle in regard to their storage is that the sooner a log is made into veneer after being taken from the living tree the better will be the results. Season checks and cracks have less opportunity to develop. Decay, particularly in the heartwood and along the season checks, is largely prevented, and therefore much waste in sawing off the ends of the logs is eliminated. But especially for ease in cutting the veneer in the slicer and rotary cutter is it desirable to have the logs fresh and full of sap. This condition is most important in the case of gums, maples, birches, and woods with sweet sap.

Methods of Cutting

The three general processes by which veneer is produced from the log are rotary cutting, slicing and sawing. Of these methods the most important is rotary cutting in which the log is placed in a large lathe and the veneer cut tangentially in a continuous sheet. About 70 per cent. of all veneer, including all the cheaper grades, is cut in this manner. The finer woods like walnut, maple and mahogany are usually quarter cut, that the full beauty of their grain may be obtained. In this case slicing or sawing must be resorted to. However, some logs of gum and poplar give bastard (tangential) cuts of very striking figure. Where quarter-cut veneer thinner than 1/32 inch is desired it must be cut by a slicer. Small logs of the more expensive woods, that would be quarter cut if possible, must be rotary cut in order to get widths which are of any value.

The preparation of the logs varies with the process used. For slicing and rotary cutting steaming is required, while for veneer sawing and slicing it is necessary to saw the log longitudinally into a number of wedge-shaped pieces.

Rotary Cutting

With all woods which contain frost, or which are dry, steaming is necessary, as it is with the harder woods, but unless the thickness of the veneer exceeds about 3/16 inch most soft species that are fairly fresh may be rotary cut without preliminary steaming. (A description of steaming bins and the routine followed in the process will be given later in connection with slicer cutting.) As the logs come from the steam bins they are barked, and any irregularities on the surface, such as projecting swellings or overgrown limb stumps are trimmed off. They are then cut to the desired length in a large cross-cut saw and the ends squared. The center of each end is carefully located and then the log is picked up by a derrick, swung into position, and centered in the rotary cutter, as shown in Fig. 1.

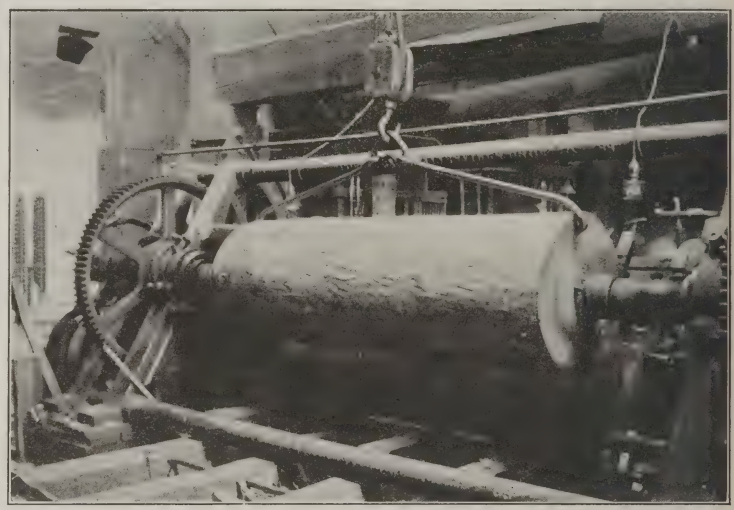


Fig. 1—Centering of log in rotary cutter

A cutter of this type is in effect a huge wood-turning lathe, with a long stationary knife fixed in position behind the log, its cutting edge at the same elevation as the axis of the chuck and spindle. Fig. 2 shows clearly the relative arrangement of the parts. The spindle into which the chuck fits is threaded for part of its length, so that when turned by a certain train of gears it advances and drives the spurs into the ends of the log, which must be very firmly gripped. Slightly forward of and above the main blade will be noticed several small adjustable knives in planes at right angles to the long knife. These are for the purpose of cutting the sheet of veneer into whatever lengths are required. The points of these knives meet the log just before it reaches the horizontal knife and cut shallow, narrow grooves around its circumference. The size of chuck used depends partly on the diameter of the log and partly on the amount of decay in the heartwood. The spurs must obtain a hold in sound wood. Since the smallest chuck is 6 inches in diameter, at least 6½ inches of log must necessarily be wasted. But, owing to the unsoundness that is usual in heartwood, this is but a slight disadvantage. In fact, it might be mentioned in passing that one of the important advantages of rotary cutting over slicing or sawing is the small influence that center decay has on the value of a log. For in the latter processes the log must be sawn into sectors, and serious decay at the center very materially reduces the width of the sheet that can be obtained.

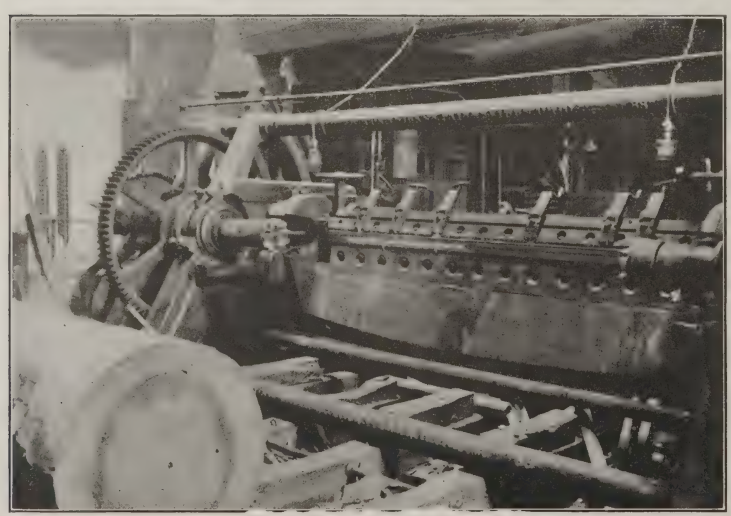

Fig. 2—Front view of rotary cutter

The sheet of veneer comes out at the back of the machine through a slot just below the edge of the long cutting knife, as shown in Fig. 3. The rate at which the veneer is cut varies as the diameter of the log because the rotary speed of the cutter, though slightly lessened when the load is excessive, is approximately constant at about 28 r. p. m., giving to the log a peripheral velocity depending on its size.

Veneer Sizes.—The maximum length to which veneer may be cut is limited by the size of the knife. The greatest length in use at the present time is 16 feet; however, the majority of knives are less than 8 feet 6 inches. With a long log the pressure of the knife acting on a large unsupported length tends to cause the log to chatter near its center. For this reason greater wastage occurs, owing to the impossibility of cutting the log to a small diameter. The sheet of veneer may be cut to any desired width if care is used to avoid breaking it in handling. Widths of 20 to 30 feet should be obtained without difficulty unless the veneer is very thin. In the preceding description the term "length" refers to the dimension parallel to the direction of the grain, and the term "width" to that perpendicular to this direction. With soft woods, thoroughly steamed, veneers up to ⅜ inch thick may be obtained, though a better maximum is 5/16 inch. In the case of oak, mahogany or maple not more than a ¼-inch thickness can be expected. On the other hands, these harder woods, with a tough fibre and fine grain, can be cut to a minimum thickness of 1/64 inch, while for poplar and gum 1/32 inch is a minimum value.

Minimum thicknesses are limited chiefly by breakage in handling, and during the past year special methods have been devised that partly remedy this difficulty.

The crew of a rotary cutter consists of five men, including one operator and two chippers. The latter catch the veneer as it falls from the knife, carry it back from the machine until the required width is reached, and then cut it off. It is necessary to obtain a given dry width, to allow for a certain shrinkage from the wet width. This increase for gum is 1½ inches per foot, for poplar 1¼ inches, and for oak 1 inch. The other two men of the crew are needed for the work of steaming and preparing the logs.

Preparation of Logs for Sawing and Slicing

Steaming.—If logs are to be cut into veneer on a slicer they must first be steamed. This operation is carried on in large bins which, if below ground, are generally of concrete, if above ground of wood with walls 6 or 7 inches thick. The rough logs are lowered by a derrick into these bins on which heavy wooden covers are then placed and tightly clamped down. Steam is now turned on. Most woods, except oak and mahogany, require steaming only over night, but with the latter 18 hours is usually needed. The size of the logs and the amount of frost they contain are factors in determining the duration of the steaming and the pressure necessary. For poplar, gum and walnut low pressure steam is sufficient, while the denser, harder woods must have steam under somewhat greater pressure. If the operator desires to accelerate the process he may do so by employing higher pressures. Some latitude is permissible in both the time and the pressure and the operator may exercise his judgment. In all cases the frost must be taken out, and after that a few woods, like walnut, unless fairly dry, need only warming through.

Sawing the Logs.—The logs are first barked and trimmed, and then placed on the carriage of a large band-saw, so that the saw will pass directly through the center of the log at each end. The carriage is seen in the foreground of Fig. 4 in its relation to the edging saw at the extreme left, and the veneer saws in the background. The sawyer next determines into how many "cants" or "pies," C, (Fig. 5) it is best to cut each half the log, his decision being based on the size and location of any defects that may be present on the diameter of the log, and on the width of the veneer desired. The cants are held by dogs on the carriage and trimmed to the flitch "F" by cutting off the corners "D," the heart, if defective, and one or two boards "E." Frequently it is necessary to saw the entire cant into boards if it appears unsuitable for veneer. The boards "E" are taken at once to the edging saw and trimmed. The waste parts are generally removed and used for fuel. The flitch "F" is now ready for either the veneer saws or the slicers.

For all quartered work the log is so placed that the cuts are radial. Occasionally, however, as with walnut, gum or poplar, in which there is no special quartered figure, flitches are prepared for bastard sawing or slicing.

A band saw crew consists of four men, the expert sawyer and three helpers, one of whom runs the edging saw for trimming up the boards.

Slicer Cutting

This process is not in such extensive use as either rotary cutting or veneer sawing, yet it has certain advantages within its own field. The chief of these, perhaps, is that the entire flitch can be utilized, whereas in veneer sawing, in spite of the thin saw employed, from 30 to 60 per cent. is wasted in saw kerfs. This becomes an important item when the wood is an expensive mahogany, curly maple or walnut. Again, if quartered veneer less than 1/30 inch thick is desired it must be cut on a slicer, for that is a minimum thickness for veneer sawing.

In slicer cutting the wood is sawn into flitches, as described above, for either quarter or bastard slices. Soft woods like poplar, especially when full of sap, do not require steaming, unless the veneer is more than 1/16 inch thick. Other woods, in a similar condition, need not be steamed if less than 1/32 inch thick, but all wood when full of frost or when dry must be steamed, particularly oak and mahogany.

Reference to Fig. 6 will help to make clear the construction of a slicer. It consists of two principal parts—the stay log, a heavy casting with a broad vertical face with grooves in which are mounted adjustable dogs that grip the flitch, and opposite this a heavy ribbed casting holding the knife. The stay log, with the flitch, is given a reciprocating motion that is forward and downward in its positive direction while the knife is stationary and slightly inclined upward, with the cutting edge of the blade up. The knife is narrow, ordinarily not more than 14 feet long, and rapidly increases in thickness from the cutting edge to give a strong and rigid backing to the latter. Through a "pressure bar" running parallel to the knife, and regulated by a hand wheel, the thickness of the veneer is controlled. This wheel is graduated along the rim, and turns past an index. One complete turn increases or decreases the thickness ¼ inch, and fractional turns change the thickness proportionally. It is impossible to cut the entire flitch into veneer, as about ¾ inch is required by the dogs that grip the flitch. If the latter is heavy or of very hard wood this unused width often increases to 1 or 1⅛ inch.

Veneer Sizes.—The maximum length of flitch that can be handled is determined by the length of knife in use, which is usually 12 to 14 feet, rarely as much as 18 feet. The softer woods may be cut to a thickness as great as ¼ inch when thoroughly steamed. The ordinary minimum thickness for any work is 1/96 inch, which, by careful adjusting, alignment and sharpening of the knife, may be decreased to 1/120 inch. Of course, only hard, fine-grained woods can be used for very thin veneer, with the exception of Spanish cedar. The maximum width is two feet. However, when great widths are wanted the maximum length is decreased somewhat.

Three men compose a slicer crew, the operator at the wheel regulating the pressure bar, and two helpers who place the strips of veneer on a table as they fall from the knife.

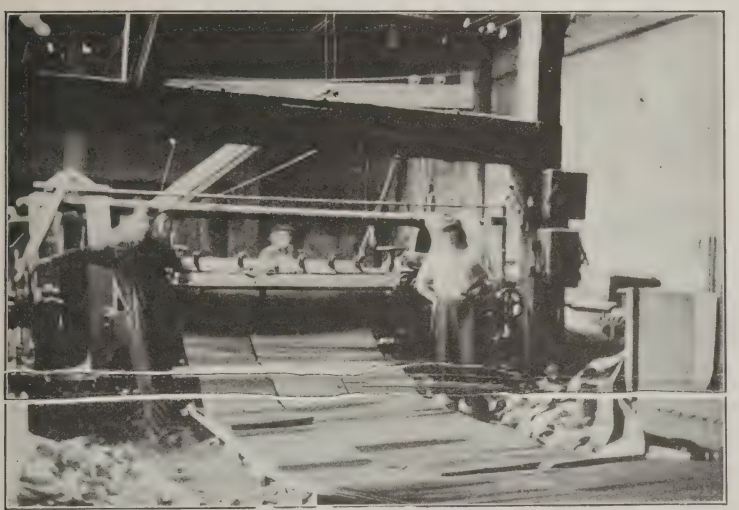

Fig. 3—Rear view of rotary cutter

Veneer Sawing

This process, possibly because of its simplicity, is more widely used than slicing for the production of quartered veneer. As is illustrated in Fig. 7, the flitch is firmly held by numerous dogs or clamps which slide up and down in grooves in a heavy stay log. This stay log, like the usual carriage of a saw, travels back and forth, carrying the flitch against the saw. This is circular with its cutting edge made up of several segments of thin steel securely bolted to the heavier steel casting which stiffens and supports the cutting segments. A kerf 1/16 inch wide is made by such a saw and, as in a slicer, at least ¾ of an inch of the flitch is required for the dogs to grip.

The sheets of veneer as they are sawn off are piled in order, and when the flitch is finished the top sheet is marked with the number of the log for purposes of later identification, a procedure which is also followed with veneer cut in a slicer.

Veneer Sizes.—The maximum length it is possible to cut is dependent on the extreme travel of the stay log. With some saws this is 24 feet, but 14 to 16 feet is the more usual limit of travel. A minimum thickness is 1/32 inch, though in ordinary practice 1/28 inch is better. A maximum width is about 18 to 20 inches. Since for quartered work the diameter of the log must be at least twice the width of the veneer, and if the heart is unsound as much as three times the width, it can be seen that for veneer sawing large and consequently expensive logs are used.

Three saws, with a total crew of five men—one expert, two sawyers and two helpers—constitute an efficient working unit. Since two men are required to operate a saw most effectively, and since it frequently happens that one of the saws has to be stopped for repairs or sharpening, this arrangement makes it possible to keep two saws busy continuously, with the expert occasionally running a third. A band-saw crew of four men is able to turn out enough flitches to keep such a unit supplied.

Drying Veneer

After the veneer has been cut by one of the

AMERICAN AERO ENGINES

By G. DOUGLAS WARDROP, M.S.A.E., A.S.M.E.

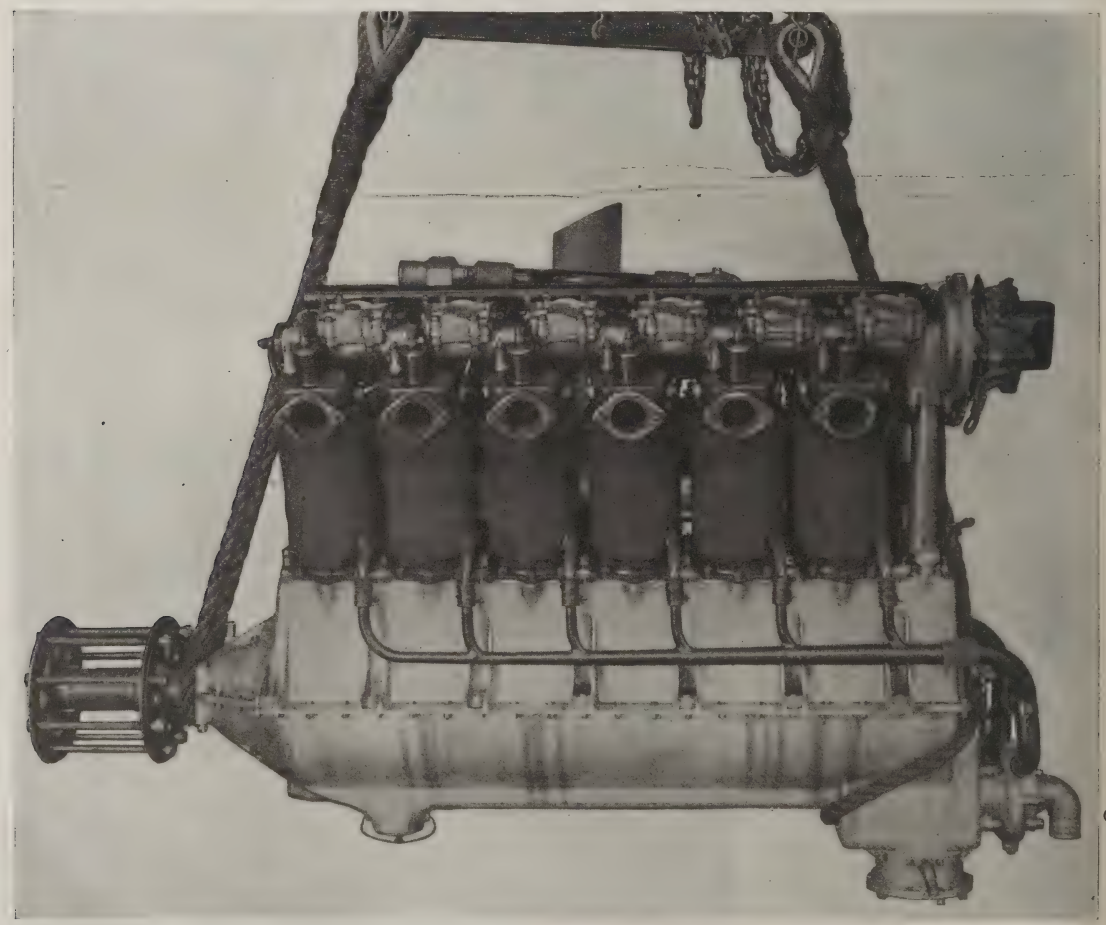
THE LIBERTY TWELVE

THE Liberty "Twelve" was comprehensively described for the first time in AERIAL AGE for December 16 and 23, with complete illustrations. It was the one purely American aeronautic contribution that got into large production, and was hailed by our Allies as an eminently useful power plant.

General Data:

Number and arrangement of cylinders	Twelve-Vee
Included angle	45°
Bore	5″
Stroke	7″
Stroke-bore ratio	1.4:1
Area of one piston	19.635 sq. in.
Total piston area	234.62 sq. in.
Swept volume of one cylinder	137.445 cu. in.
Displacement of motor	1649.5 cu. in.
Compression ratio (Army)	5.4:1
Compression ratio (Navy)	5:1
Normal brake H. P.	400 at 1750 RPM
Type of valve gear	Overhead cam shaft and valve rockers
Number of carburetors	Two Duplex Zenith

Lubrication:



Type	Forced feed
Type of pumps	Rotary gear
No. of Pumps	1 double pressure and 1 scavenging
Ratio of pump speed to crankshaft speed	1.5:1

Ignition:

Type	Battery and generator
Firing order	L 1-9-5-11-3-7, R 8-4-12-6-10-2
Number of plugs per cylinder	2
Type of plug	A. C.
Ratio of generator speed to crankshaft speed	1.5:1

Cooling System:

Type	Water cooled
Pump	1 centrifugal
Diameter of inlet pipe	2″
Diameter of outlet pipe	1⅜″
Number of outlets	2
Diameter of rotor	3⅛″
Ratio of pump speed to crankshaft speed	1.5:1
Water temperature inlet	155° F.
Water temperature outlet	175° F.

The Liberty Motor

THE KING-BUGATTI

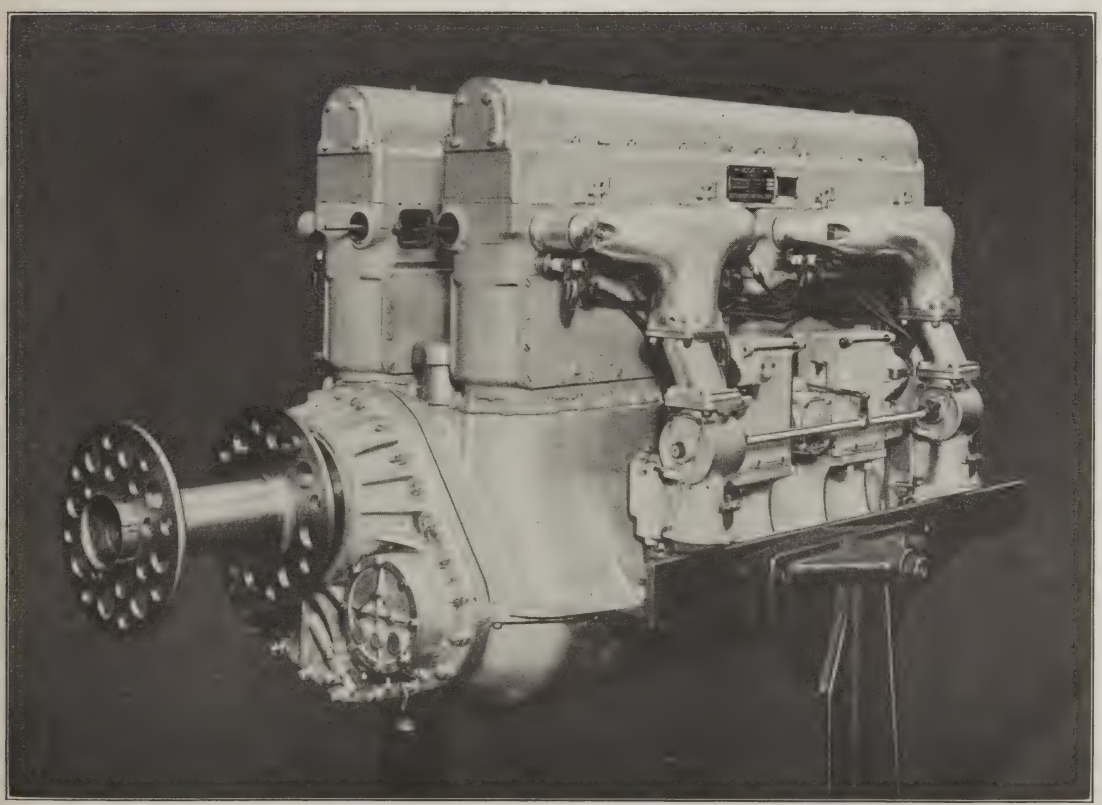
IN our issues of February 10 and 17 we presented to the engineers of the automotive industries the first complete discussion of the re-design and manufacture of the Bugatti engine in America, which was destined to be of very great value if the war had continued until the present spring. It was the first power plant designed to permit of the mounting of a 37 millimeter gun, which fired its shells through the hub of the propeller.

In re-designing the motor Charles B. King, to whom the work was entrusted, made very many improvements, and on the various tests made at the plant of the Duesenberg Motors Corporation, at Elizabeth, where it was manufactured, it showed marked efficiency.

General Data

Number and arrangement of cylinders
16 vertical, 2 rows of 8 in blocks of 4
Material ..... Cast iron
Bore ..... 4.33" 110m.m.
Stroke ..... 6.3" 160m.m.
Stroke-bore ratio ..... 1.435 :1
Area of one piston ..... 14.725 sq. in.
Total piston area ..... 235.6 cu. in.
Swept volume of one cylinder ..... 92.768 cu. in.
Displacement of motor ..... 1484.288 cu. in.
Compression ratio ..... 5 :1
Normal brake H. P. ..... 410 at 2,000 R.P.M.
Type of valve gear.... Overhead camshaft and valve rockers
Number of carburetors ..... Four Miller special
Ratio propeller to crankshaft speed ..... 666 :1

Ignition



Type ..... Magneto
Number 4
Make ..... "Dixie 800"
Firing order: 1L, 7R, 5L, 4R, 3L, 8R, 7L, 2R, 4L, 6R, 8L, 1R, 2L, 5R, 6L, 3R
Number of plugs per cylinder 2
Type of plug ..... Titan A. C.
Advance ..... 38°
Magneto rotation ..... Clockwise

Cooling Systems

Type ..... Water cooled
Pump ..... 1 centrifugal
Inside diameter of inlet and outlet elbow to cylinders..... 1½"
Number of inlets 2
Number of outlets 2
Water temperature inlet ..... 150° F.
Water temperature outlet ..... 160° F.

Lubrication

Type ..... Forced feed and spray
Type of pump ..... Rotary Gear
Number of pumps ..... One pressure, one scavenging
Oil pressure ..... 30 lbs.

The sixteen cylinder King-Bugatti aviation engine

THE CURTISS K-6 and K-12

IN the design of Curtiss K-6 and K-12 motors, the form of construction adopted gives a minimum centre distance between cylinders, together with careful placing of the accessories, makes the motor compact and easily placed in the fuselage, at the same time the accessibility of the various parts is such that sub-unit may be readily inspected or overhauled without disturbing the motor in the aeroplane.

Gear Reduction

The gear reduction of the Model K-12 raises the centre of thrust to a point near the centre of gravity, and close to the centre of projected area. This enables the design of the nacelle or fuselage to be reduced in size, with consequent lower head resistance.

Ignition

Double ignition, from the two separate magnetos, gives a more instantaneous explosion, which at high engine speed is necessary to develop high mean effective pressures. The spark plugs are located near the intake valves, on the upper side, to guard against fouling and insure absolute ignition. The wire assemblies are enclosed in insulating covers of micarta, which guard against short circuit and injury.

Carburetion

A duplex carburetor (K-12 is provided with two carburetors), each tube supplying one set of three cylinders, assures a more satisfactory charge than a single carburetor equipment, due to the separate manifolds which prevent starving and eddying, and the better vaporizing properties of two small carburetors over one large one. In addition, hot water jackets are provided on the manifolds to assist in vaporizing the gasoline.

Lubrication

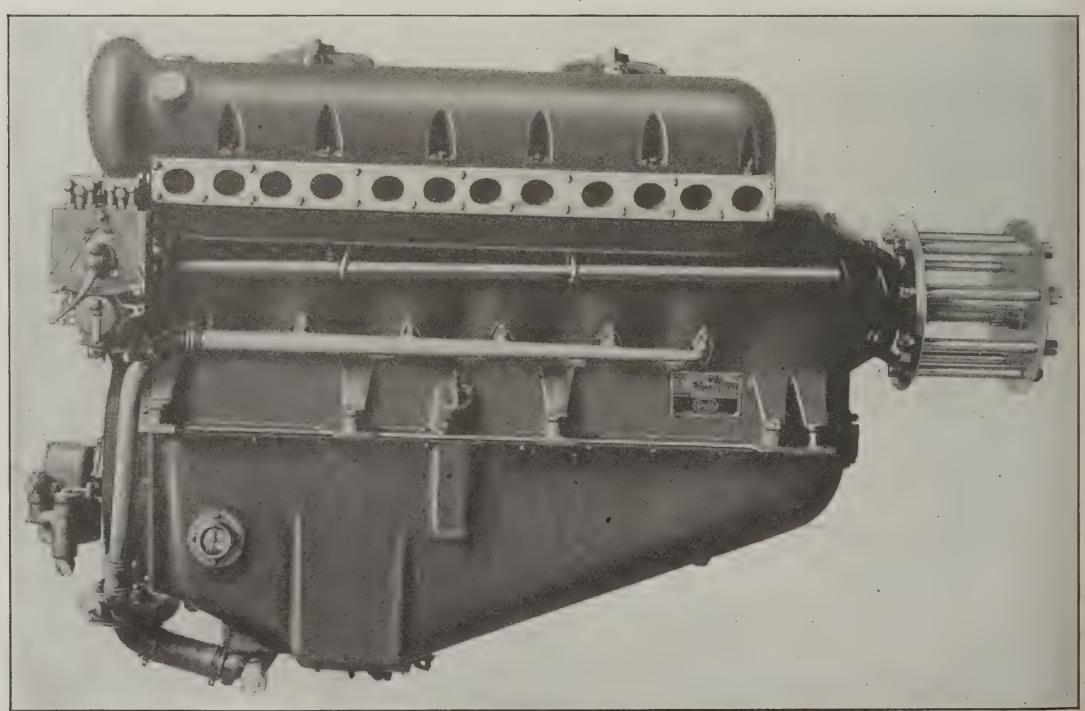
Pressure feed through crankshaft, propeller shaft and cam shafts, insures a continual film of clean oil on all bearings. Separate return pump with double intake absolutely prevents accumulation of oil in either end of pan, and consequent flooding of cylinders when machine is climbing or gliding. Pressure adjustment permits of individual adequacy of oil feed on each motor, and change for wear and varying conditions of service.

Type of Motor

K-6 is a six-cylinder water cooled—cylinders en bloc— aluminum construction. K-12 is a 12-cylinder motor with a 5:3 gear reduction to propeller shaft.

Horse Power

K-6 rated at 150 H.P. at 1,700 R.P.M. K-12 rated at 375 H.P. at 2,250 R.P.M. at crankshaft.



Bore and Stroke

4½" x 6".

Weights (Lbs.)	*Model K-6*	*Model K-12*
Cooling Water in Motor	—	38
Basic Motor	346	589
Carburetor and Intake Manifold	18	37
Ignition Equipment	32	37
Water Inlet Lines	4	4
Exhaust Manifold	14	28
Hand Starting Crank	3	—

Gasoline Consumption

Fifty-five lbs. per H.P. Hour.

The Curtiss Model K-12 aviation motor

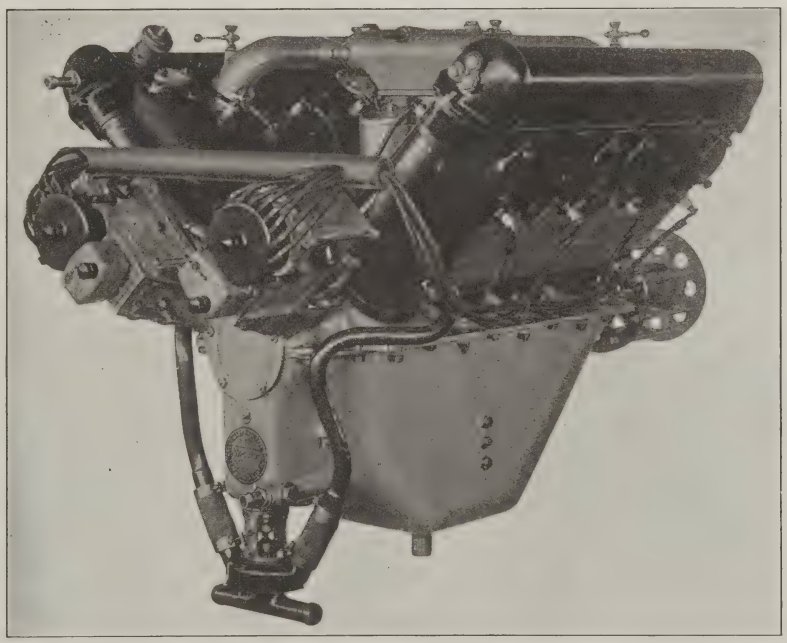
THE HISPANO-SUIZA

THE Hispano-Suiza engine has been used in far larger quantities by the allied arms than any other motor and has been produced in much greater numbers than any other design of aeronautical engine.

It has been built in France, Spain, England and America, and is about to be made in Japan. Originated in Switzerland and Spain through the old Hispano-Suiza Motor Car Co. by Marc Birkight, the engineer and general manager of the company, it was quickly taken up by the French Government, being an engine which at that time was exceptionally light for its power and was also very easy to manufacture by comparison with the rotary motors and with the majority of the water-cooled fixed cylinder engines of French or British origin. For France it did so well in the air that a large number of French factories were ordered to drop their own experiments and devote all their energies to Hispano-Suiza manufacture. At the signing of the armistice there were seventeen plants in France wholly given over to Hispano work.

Meanwhile one of England's largest automobile plants had been taken over by the British Government to make a slightly modified copy of the French motor and the Wright-Martin Aircraft Co. of New Brunswick, N. J., had started to make an exact copy of the French engine, for France, before the U. S. entered the war.

The latest products of the Wright-Martin Company were completely described and illustrated in AERIAL AGE for December 30, 1918, and January 6, 1919.



During the period from June, 1917, till the end of that year, Birkight went on with experimental work on the 300 h.p. and H. M. Crane, Vice-President of the Wright-Martin Aircraft Co., also proceeded with a design which, while it embodied most of the French features, yet differed in some very important points. When placed on test last Spring at the Bureau of Standards at Washington, and later at McCook Field, Ind., this Crane motor showed substantially more power than the French engine with the same bore and stroke and had a much lower oil consumption. It was also easier to manufacture in several details, and was stronger than the French engine, making for greater durability. The weight was slightly greater, but the power to weight ratio was slightly better in the American design.

In course of developing the 300 h.p. sundry small discoveries were made which led to alterations in the smaller motors then in production at New Brunswick, so that at present the 150 h.p. and the 180 h.p. American Hispano engines are quite distinct from the French motors of the same rated power and cylinder dimensions. The differences are, however, matters of detail and are not such as to prevent interchange of American and French engines in the same plane.

In all there are four types of Wright-Martin Hispana motors. Model A is the original and is a copy of the French 150 h.p. precisely. Model I is the improved 150 h.p. which for some time past has been supplied for American training planes.

Next comes the 180 h.p., which is known as Model E and is identical with Model I, except that the pistons are different, giving the higher compression. Finally there is the 300 h.p. or Model H.

All four engines are eight-cylinder V type with 90 degrees between the blocks, and each of the three smaller ones have the same piston displacement, their bore being 120 mm. or 4.72″ and stroke 130 mm. or 5.11″. Models A and I develop 150 h.p. at 1,450 r.p.m. Model E develops 185 h.p. at 1,750 r.p.m.

The Wright-Martin Hispano-Suiza

THE DUESENBERG MODEL H

THE Model H Duesenberg motor, developing 850-900 horse power, built by the Duesenberg Motor Corporation, of Elizabeth, N. J., is the most ambitious aero engine development that has been attempted, and carried through successfully, in the United States. It was fully described in AERIAL AGE for January 27, 1919. It was designed by F. S. Duesenberg, the pioneer builder of automobile speed engines, and he had the able assistance and coöperation of William Beckman. The motor is of the sixteen-cylinder V type, with the cylinders at an angle of 45°, and the weight of the power plant with gear drive is 1,575 lbs., without gear drive, 1,390 lbs.; remarkably low weight ratio for a power plant of its power.

General Data

Number and arrangement of cylinders	Sixteen V
Included angle	45°
Bore	6″
Stroke	7½″
Normal Brake Horsepower	800 at 1,800 r.p.m.
Type of gear	Overhead camshaft and valve rockers
Number of carburetors	Four Miller

Lubrication

Type	Forced Feed
Type of pumps	Rotary Gear
No. of pumps	1 double pressure and 1 scavenging
Ratio of pump speed to crankshaft speed	1 to 1

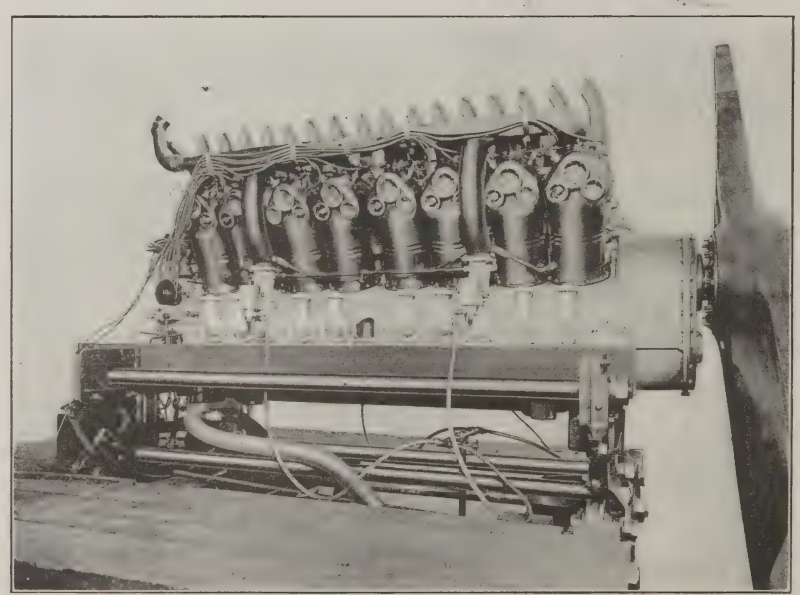
Ignition

Type	Battery and generator
Firing order	L: 4-8-8-2-6-1-5-3-7; R: 1-5-3-7-4-8-2-6
Type of plug	A. C.
Ratio of generator speed to crankshaft speed	2 to 1

Cooling System

Type	Water cooled
Pump	1 centrifugal
Diameter of inlet pipe	1⅝″
Diameter of outlet pipe	1⅜″
Number of outlets	2
Diameter of rotor	5¾″
Ratio of pump speed to crankshaft speed	1 to 1
Water temperature inlet	125 F.
Water temperature outlet	155 F.

Valves



Number per cylinder	One inlet and two exhaust
Outside diameter	Exhaust 2-3/16″, Inlet 2-5/16″
Port diameter	Exhaust 1-31/32″, Inlet 2-23/32″
Width of seat	7/64″
Angle of seat	30°
Valve lift (inlet)	9/16″
Valve lift (exhaust)	½″
Diameter of stem	Inlet ½″, Exhaust 7/16″
Length of valve	Exhaust 6-27/32″, Inlet 6⅞″
Number of springs per valve	Two concentric
Length of springs in position	Outer 2⅞″, Inner 2¾–
Mean diameter of coils (large spring)	1⅛″
Mean diameter of coils (small spring)	1″
Inlet rocker clearance	.010
Exhaust rocker clearance	.015

Cylinders

Overall height of cylinders	19-1/16″
Length of projection in crankcase	2¾″
Diameter of cylinder over water jacket	6-27/32″ min.
Diameter of cylinder over water jacket	7-7/32″ max.

The ignition mountings permit of any standard make magnetos being used and recent motors have been equipped with two 8-cylinder Dixie magnetos of fixed spark and Delco special distributor with battery current furnished by Delco and Liberty generator. The Pilgrim battery ignition system has been tested on this engine also with very successful results.

In the cooling system the water is delivered from the pump through two 1⅞″ diameter tubes which connect to two headers or manifolds, one along each side and one located directly under the valves near the top of the cylinders. This header is joined to the cylinder by means of the outlet connections. At each cylinder where the water enters is welded a distributor which leads two streams of water, one directly beneath each exhaust port and a third stream to the outside of the cylinder wall or barrel.

The Duesenberg Model H 850-900 H.P. motor

THE LAWRANCE 60 H.P. AIR COOLED ENGINE

THE Lawrance Model L-1 is a three-cylinder Y-type air-cooled engine rated at 60 h.p. at 1,900 r.p.m. The accompanying graph shows that the engine delivers 30 h.p. at 800 r.p.m. and 63 h.p. at 2,100 r.p.m.

Bore, 4.25 inches; stroke, 5.25 inches. Cylinder displacement, 225 cubic inches. The weight complete with propeller hub, 130 pounds. This weight includes everything necessary for running, with the exception of the oil tank and mounting plates for which an additional weight of nine pounds is allowed. Starting handle is supplied when desired. Exhaust pipes made to individual requirements.

Cylinders

The cylinders are of cast aluminum with cooling fins machined. Shelby steel liners with walls 1/16 inch thick are cylinder and the crankcase. Liners are case-hardened and ground, which gives them a very fine wearing surface.

Each cylinder is attached to the crankcase by means of six studs.

Pistons

Pistons are of cast aluminium alloy. Crowns are flat. Each piston has four concentric cast iron rings and one wiper ring on skirt.

Crankcase

Crankshaft is of chrome nickel-steel. It has a single throw and is counterbalanced. The shaft is hollow for lubrication.

Front end of shaft is tapered to receive the propeller hub which is drawn tight by means of a differential thread nut. The shaft is sturdy and of large dimensions throughout.

Connecting Rods

Connecting rods are of chrome nickel-steel. They are round, of constant section and hollowed for lightness. They are machined all over. Each of the three rods has a segmental shoe which floats in two grooves in the big end bearing.

Bearings are of cast bronze with Babbitt lining.

Wrist pins of nickel-steel float in both the rods and pistons. Bronze buttons on the ends of wrist pins keep them from working out sidewise.

Valve Gear

Valve gear consists of three individual camshafts, each with two cams. The push rods are adjustable.

Rocker arms are provided with rollers where they come in contact with the valves so that all side thrust on the valve guides is eliminated.

Valves are of Tungsten steel, 2 1/16 inches in diameter.

Exhause valves are mercury treated so as to more readily conduct the heat from the head of valve to the stem.

Guides and valve seats are also of cast bronze, set into heads of the aluminium cylinders.

Springs are of a new type. They are conical in shape, wound of flat steel placed edgewise and tapered so that the greater width is in the large coils and lesser width in smaller coils. This permits of a shorter spring than would be possible with the usual helical coil spring.

Ignition

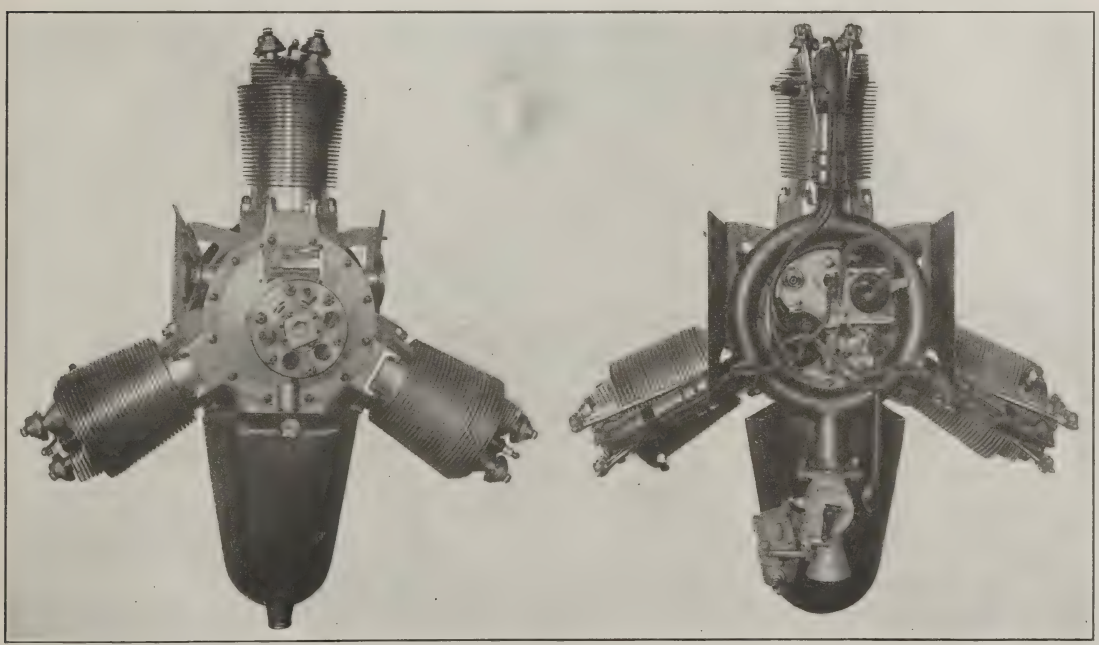
Two kinds of ignition are supplied. One type is a magneto designed by Mr. Kilsrath of the Simms Magneto Company which has a single breaker and one primary winding but two high tension windings, giving two absolutely synchronized sparks.

Magneto is run at 1½ times engine speed. The high tension distributor is separate and driven off one of the crankshafts.

The other ignition system is the "Philbrin," designed by the Philips-Brints Ignition Company. This system has a dual spark with two breakers; either one is used to fire the entire system; allowing perfect synchronization.

One of the accompanying illustrations shows the magneto in place.

Carburetor



A Miller Carburetor is used. It has a throat 1¾ inches in diameter.

Lubrication

Lubrication is by means of pressure supplied by a gear pump. Pressure is maintained at 25 pounds per square inch.

The oil is fed through the rear of crankshaft to the front cover where it runs to a check valve which maintains the necessary pressure. From this valve the oil drains back to the tank immediately below it. On the front cover plate, the by-pass valve operates at a pressure of 50 pounds. It might seem that the two lower cylinders would obtain most of the oil but as a matter of fact it has been proven that the oil is evenly distributed to the 3 cylinders.

Oil is consumed at the rate of .07 lbs. per h.p. per hour.

The Lawrance 60 H.P. air cooled aero engine

THE UNION 6-CYLINDER AEROMOTOR

THE six-cylinder Union Aeromotor, manufactured by the Union Gas Engine Co., of Oakland, California, has many interesting features. It was first fully described in AERIAL AGE for July 9, 1917, and since that time has been wonderfully developed and improved.

General Description

Type—Six (6) cylinder, vertical, four-cycle, water-cooled, valve in head.

Power—120 h.p. at 1,350 r.p.m.

Weight—Engine with two carburetors, two magnetos, pumps and water piping, weighs 485 lbs.

Cylinders—Cylinders are of steel, with semi-steel head for valves and spark plugs. Base flange integral with walls of cylinder. In test, these cylinders when held by base flange only, withstood a hydraulic test of over 1,200 lbs. per square inch, or a total pressure on the head and base flange of over ten tons.

Cylinder water-jackets are of copper, with brazed joints. Upward thrust of cylinders is taken by chrome nickel studs extending from main journal caps to cylinder flanges.

Valves—Valves are of E. W. P. alloy. Stem guide is long, and water-cooled for its entire length. Valve springs are double, concentric, and of the helical type, right and left-hand.

Rocker Arms — Rocker arms are machined from solid chrome-nickel steel forgings, and heat-treated. Bearings are ¾" diameter and 2½" long. Shape of arms is such that oil leakage is prevented without the use of packing. Excessive wear of valve stem end, caused by point contact of adjusting screw, is eliminated by having line contact in place of points; length of contact between rocker end and valve stem being ⅜". Valve clearance is obtained by use of small cap with thin discs on end of stem. Cap is held by cotter so that adjustment is positive.

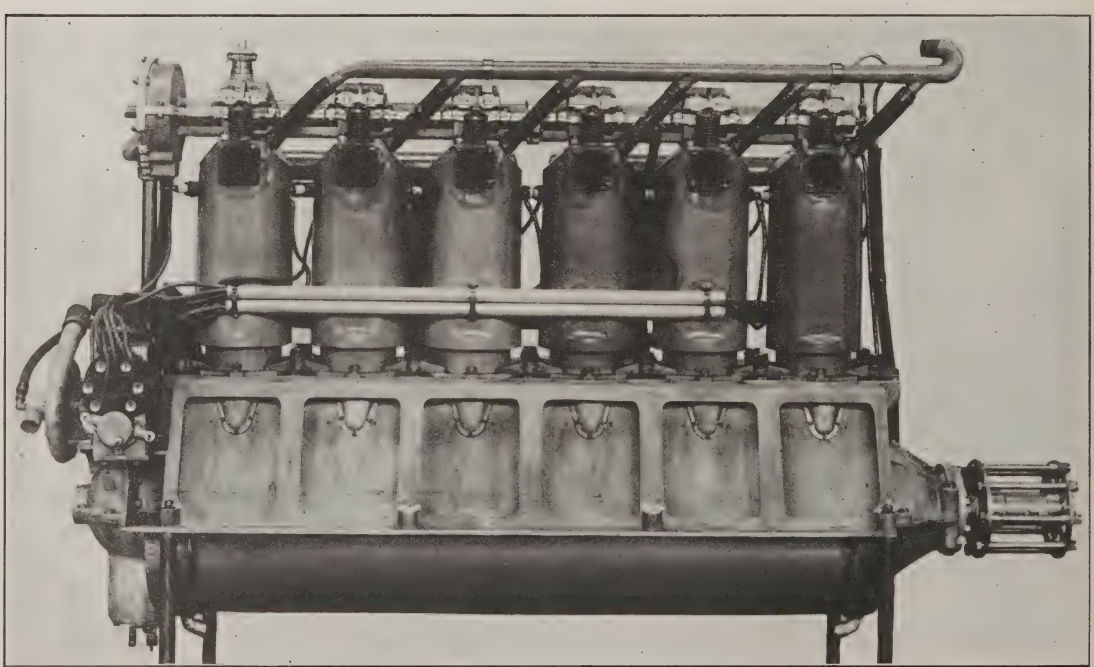
Camshaft Housing—Camshaft housing is split horizontally along the center line of the camshaft, permitting easy removal of shaft. To prevent flooding of camshaft housing when climbing, a drain from each end of housing leads down to main crankcase sump.

Camshaft Gears—All valve gears are of Midvale chrome nickel steel, heat-treated and operate in oil bath.

Magneto and Pump Gears—See camshaft gears.

Pistons—Pistons are of Lynnite aluminum alloy. Piston length is 6". Piston pin bearing is 1¼" x 2¾".

Connecting Rods—Connecting rods are I-beam section, of Midvale chrome nickel steel, heat-treated.



Crankshaft—Crankshaft journals are 2½" diameter by 2½" long; crank pins are 2½" diameter by 3" long. In addition to the seven main bearings, there is a bearing just outside of the thrust. Shaft is made of Midvale chrome nickel steel, heat-treated.

Thrust Bearing—Propeller thrust is taken by a two-way, self-aligning SFK bearing.

Crankcase—Crankcase is of aluminum alloy, and in addition to thorough cross-webbing, the side walls are of hollow box section. The stiffness of this construction is so great that the entire propeller torque can be taken through the length of the case without any signs of twisting or vibration, the case during this test being held from rotating at the end opposite to the propeller end only.

Lubrication—Oil is taken from the crankcase by a gear pump, delivered to a combined oil tank and cooler (located where convenient), from which it flows back to a second gear pump which sends it under a pressure of 40 to 90 lbs. to the crankshaft journals, through the shaft to the lower rod bearings and up into the piston pin. The holes in the piston for the piston pin being sealed, the oil must pass between the outer surface of the pin and its bearing. From here it is carried to the cylinder walls. The camshaft, camshaft bearings, cams, rocker arms and valve gears are lubricated by oil bypassed from the oil pressure regulator. This insured force-feed lubrication to all moving parts, even with no oil in the crankcase.

Ignition—Current is furnished by two entirely independent magnetos of either Berling or Dixie make. Each cylinder is fitted with two plugs, each plug being in close contact with a water-cooled wall for its entire circumference.

The Union 6-cylinder Aeromotor

THE KNOX TWELVE

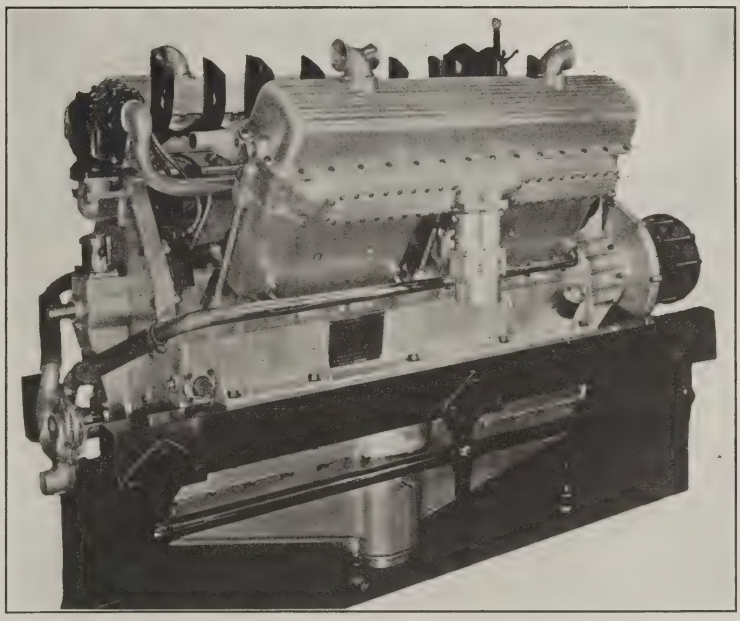
WHEN the Knox 300 H.-P. aero engine had its first block test in November, 1916, it was then the largest power plant that had been constructed in America. Development of the motor was retarded during the war owing to the other war contracts which the Springfield Motors Company had.

The original model was a 12-cylinder, 4¾ inches bore by 7 inches stroke and is a "V" engine with six cylinders on each side, set at 60 degrees from each other.

The crankcase is a special aluminum alloy casting in one piece and extending 7 inches below from the center line of the crankshaft to give barrel section for strength.

Instead of using legs for motor supports on the crankcase, as is the general practice, this engine is supported by a shelf running the full length of the case on each side of which the motor will rest. Five (5) bolts pass through each shelf into the frame work of the aeroplane and a supporting rib or brace is cast each side of each bolt. The motor is very narrow at this point and will enter a frame 15 inches in width inside with bolt centers 17 inches.

The lower half of the crankcase is an aluminum casting in one piece and is bolted to the upper half. No mechanism is contained in this lower half and there are no pipe connections to make. A glass gauge is attached to the side of the case, showing the oil level at all times.



The cylinders are special aluminum alloy castings with cast iron liners ⅛ inch thick. These liners have a flange on the lower end and are pressed in from the bottom. The cylinders are cast in blocks of three and are held to the case by eight studs each. The cylinders are open at both ends and the upper portion of the bore forms the combustion chamber, which is machined all over. The corner bosses are supported by two heavy ribs each and the central bosses run clear through between the cylinders to give strong anchorage. The water jacket extends well down below the bottom of the stroke and ½ inch water space is provided between the cylinders. The piston displacement of the motor is 1,488.53 cubic inches.

The cylinder heads are cast in blocks of six, of special aluminum alloy and cast iron valve seats are cast integral with the head. The head for each six cylinders is held down by 16 nickel steel studs passing clear through the head. There are four valves to each cylinder carried in the cylinder head and the water jacketing is so arranged that each valve seat is practically surrounded by water.

Camshafts and rocker arms are carried in the head, the camshafts having eight bearings and the rocker arms being supported above it, as is well illustrated in the photographs.

The camshafts as well as the rocker arms and all mechanism in the head is under forced feed lubrication and drainage is provided back to the crankcase at the center when the motor is in normal position and at each end when the motor is tipped up or down.

Each cylinder head has an aluminum cover which completely conceals and protects all of its mechanism.

The Knox Twelve

THE HALL-SCOTT A-8

THE A-8 is a twelve-cylinder engine of advanced design, incorporating many attractive features, and developing a brake horse-power approaching 450, with an engine weight of less than 800 pounds.

Anticipating the requirements of aeronautical warfare, Lieutenant Colonel E. J. Hall, consulting engineer of the Hall-Scott Motor Car Company, and at that time active head of its experimental and production departments, began work on this twelve-cylinder A-8 model and had completed it after exhaustive tests prior to May 1, 1917. It was placed on the testing stand for its final run when Colonel Hall was called to Washington early in May, last year, to assist the Government Aircraft Production Board in the designing of an American aeroplane motor that would meet the requirements of greater power, lighter weight, and more dependability than any of those on the market at that time.

While the Hall-Scott Motor Car Company at West Berkeley, California, had completed the assembly of this equipment, and was planning on quantity production at the time it was decided to go ahead with the United States aircraft program, the diversion of Col. Hall's efforts to the Government service, and the wish of the company not to interfere with the production of the Liberty engine, resulted in the postponement until now, of the final tests, and of putting the A-8 type Hall-Scott engine into production.

The first engine of the A-8 type weighed 1100 pounds. This was equipped with the cast iron cylinders, which were made interchangeable with the 4, 6 and 8 cylinder engines of the Hall-Scott design. The company, however, had ready steel cylinders which have been substituted for those in the original engine, and which together with refinements in other parts reduce the total weight, with a built-in electric starter, to about 800 pounds or 1.75 pounds per horse-power. Besides the cylinders, many other parts are interchangeable with those of Hall-Scott 4, 6, and 8 cylinder engines of the A-5, A-7 and L-6a types.

The bore and stroke of the A-8 Hall-Scott engine is 5 by 7 inches, the same as in the A-5, A-7 and L-6a types.

The photograph of the new twelve-cylinder A-8 engine shows it mounted on the testing block, fitted with the four-blade propeller, and illustrates very clearly the propeller hub of special Hall-Scott design.

The manufacturers anticipate a similar satisfactory performance in actual service in the A-8 type, as has marked the success of the 4, 6, and 8 cylinder machines. It is thought that the A-8, designed to meet the peculiar conditions under which American aeroplane engines must function, and to fit the American manufacturing methods, will rank in performance with the better types of foreign engines.

The Hall-Scott A-8

THE 80 H.P. LE RHONE

THE 80 H.P. Le Rhone engine was manufactured in this country for the Bureau of Aircraft Production by the Union Switch & Signal Co., at Swissvale, Pa., and was used in the Thomas Morse S-4-E and Standard ME1.

The engine consists of two elements, the fixed part and the rotating part.

The fixed part consists of a hollow crankshaft, two engine supporting plates and the carburetor. The carburetor is mounted on the extreme end of the crankshaft and supplies the vaporized mixture through the hollow shaft to the crankcase. On the main supporting plate, which is keyed to the crankshaft, are mounted the magneto, the distributor brush and the oil pump. The short end crank, formed by the extension of the shaft at the propeller end, is located on the crank pin by a taper and round key and is held by a locknut. The crankshaft is machined from high grade chrome-nickel steel forging oil tempered to give high elastic limit and weighs 59.5 lb. before and 11.15 lb. after machining.

The rotating part consists of crankcase, cylinders, intake headers, pistons with connecting rods and thrust block, valve gear and ignition distributor.

Ball bearings are used exclusively for rotating elements. There are nine sets of ball bearings on the crankshaft. All the ball bearings within the crankcase and housings are of the retainer type.

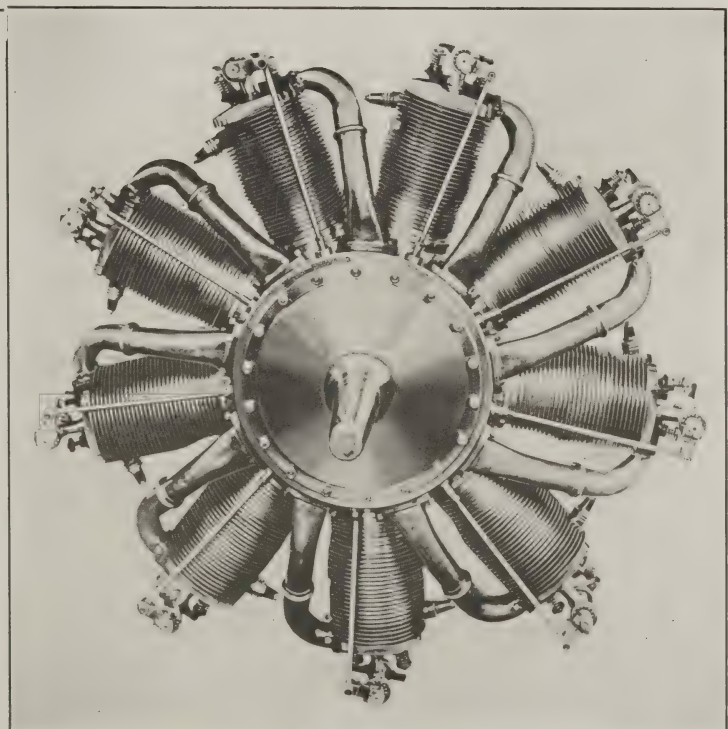
The crankcase is in the form of a steel cylinder provided with nine bosses having threaded openings into which the cylinders are screwed. It is a 40 to 50 per cent. carbon open hearth steel forging, specially heat treated and weighing 274 lb. before, and 28¼ lb. after machining. The propeller shaft is made integral with the front crankcase cover and is machined from a chrome-nickel steel forging, oil tempered. The thrust bearing housing is bolted on the rear of the crankcase, and on it are mounted the magneto and oil pump drive gear and the ignition distributor ring. The crankcase parts revolve about the shaft on three sets of ball bearings, the propeller thrust is absorbed by a double row ball thrust bearing.

The cylinder is a 40 to 50 per cent. carbon open hearth steel forging weighing 62½ lb. before and 7¾ lb. after machining, specially heat treated after rough turning and has cooling fins turned on the outside barrel and on the head. It is provided with a cast iron liner pressed into place.

The cylinder, held in the crankcase by threads cut at its base, is prevented from further rotation about its own axis by a locknut which screws down against the crankcase boss. In each engine assembly, in order to prevent vibration, such cylinders are selected as have equal weights. They must have not only equal total or static weight, but they must also have the same dynamic weight or moment about the center of engine rotation.

The two valves, with seats provided in the steel cylinder head, are actuated by an oscillating rocker arm and a single push rod, the rocker arm being supported on two ball bearings. The valves are made of chrome-nickel steel, and are provided with a screw driver slot for grinding in the 36½ deg. seat. The guide is a cast iron bushing pushed into a steel retaining sleeve which is screwed into the valve cage and held by a locknut.

The valve spring is of steel wire single coil, of 3½ lb. tension with the valve in a closed position. No spring is required except at starting; at a speed of 1,200 r.p.m. the centrifugal force acting on the valve is about 85 lb.



The copper intake headers which convey the carbureted mixture from the crankcase to the inlet valve cages are made in two pieces with a slip joint sealed by a rubber ring.

Specifications

80 H. P. Le Rhone Engine

Type of engine	Radial revolving, four stroke
Rated horsepower	80
Normal speed	1200 r.p.m.
Number of cylinders	9
Cylinder bore	105 mm. (4.1369 in.)
Stroke	140 mm. (5.5120 in.)
Piston displacement	667 cu. in.
Compression ratio	4.8 (70½ lb. absolute)
Order of firing	1-3-5-7-9-2-4-6-8
Method of cooling	Air
Diameter of inlet and exhaust valves	1.8 in.
Diameter of valve stems	0.315 in.
Lift of inlet and exhaust valves	18/32 in.
Carburetor (mixing valve with gate throttle and metering pin)	Block tube type.
Magneto	Fixed spark
Direction of rotation	Clockwise

HONOR ROLL OF THE AIR SERVICE

The following officers of the American flying arm have been decorated for conspicuous bravery in action. The list, which includes both American and foreign awards, has been carefully compiled from available official sources, but the records are not yet complete.

Distinguished Service Cross

Thomas J. Abernathy....2d Lieut
Perry H. Aldrich....1st Lieut.
Arthur H. Alexander....1st Lieut.
Sterling C. Alexander....1st Lieut.
Gardner Philip Allen....1st Lieut. C. A. C.
Flynn L. A. Andrew....1st Lieut.
Paul Armengaud....Major
Rodney M. Armstrong....1st Lieut.
Dogan H. Arthur....1st Lieut.
Benjamin L. Atwater....1st Lieut.
Walter L. Avery....1st Lieut.
Philip R. Babcock....Captain
David H. Backus....1st Lieut.
Wm. T. Badham....1st Lieut.
Paul Frank Baer....1st Lieut.
Ralph S. Bagby....1st Lieut.
Herbert B. Bartholf....1st Lieut.
Byrne V. Baucom....1st Lieut.
James D. Beane....1st Lieut.
David C. Beebe....2d Lieut.
Franklin B. Bellows....2d Lieut.
William Belzar....2d Lieut.
Otto E. Benell....2d Lieut.
Louis G. Bernheimer....1st Lieut.
Chas. Raymond Blake....1st Lieut.
Erwin R. Bleckley....2d Lieut.
Hugh D. Bloomfield....1st Lieut.
Allen F. Bonnalie....1st Lieut.
Horace L. Borden....2d Lieut.
Lloyd G. Bowers....1st Lieut.
Samuel C. Bowman....2d Lieut.
Theodore E. Boyd....1st Lieut.
Lewis H. Brereton....Lt. Colonel
Hugh Brewster....1st Lieut.
Arthur R. Brooks....1st Lieut.
Wm. E. Brotherton....2d Lieut.
Mitchell H. Brown....2d Lieut.
Harold H. Buckley....Captain
Edward Buford, Jr....Captain
Valentine Burger....2d Lieut.
James S. D. Burns....2d Lieut.
Byron T. Burt, Jr....1st Lieut.
Alan Butt....1st Lieut.

THE AERONAUTICAL RADIATOR

By S. R. SWENSON

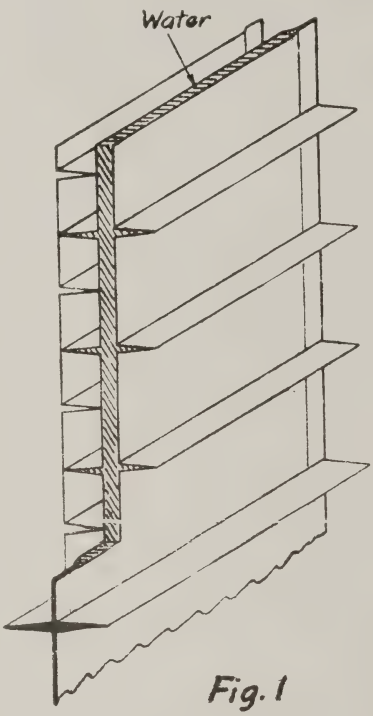
Head of Radiator Section, Division of Aeronautics, Bureau of Steam Engineering

Types in General

BEFORE going into the theory of design of the best radiator for use on aeroplanes, it is believed that the reader should be familiarized with the general types being made in this country as these are now being used for this purpose and will undoubtedly be in such use for some time to come; for, although they do not represent good design (except from the point of view of cheap and rapid production and automobile use) there is no radiator in production at the present time which can be turned to.

The commercial radiators fall almost entirely into the ribbon type. They are constructed from thin bronze or brass ribbons, which are in general passed through automatic stamping machines or rollers where they take on the desired form. A particularly common type is illustrated in figure one, this form of radiator being manufactured by several concerns, with very minor respective variations. Other forms are illustrated in figures two and three. These three types represent those in which there is not an excess of indirect radiating surface. There are also a number of types in which a very large percent of the total surface is not in contact with the water, this indirect radiating surface consisting in general of variously stamped metal ribbons inserted between the water-carrying assemblies. These latter types of radiators may be set aside immediately as being suitable only for automobile, truck, tractor and stationary use, because their ability to give up their heat to the air, at high air speeds does not compare favorably with other types, and their resistance to air flow (hereafter termed "head resistance") is apt to be high. They are therefore unsuitable for aeroplane work; and we may confine ourselves to a consideration of radiators which, when viewed from the front, *present clear, unobstructed air passages,* and in which *every individual vertical section is a water passage.*

Radiators of this type are constructed with approximately square air passages, whose sides vary from one quarter of an inch to three tenths of an inch, according to the manufacturer of the radiator. In many cases one concern builds them in two or more sizes of air passage, but the larger sizes should always be chosen, as the smaller do not as a rule dissipate any more heat at high speeds, and the radiators weigh more and present a higher resistance to the air.



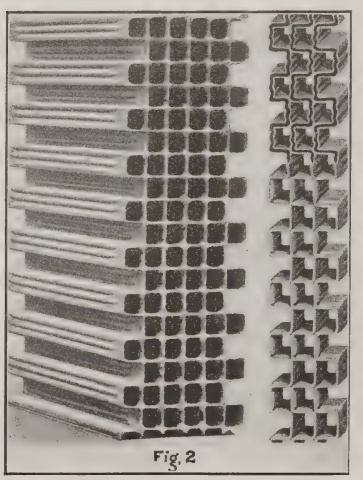


Fig. 1

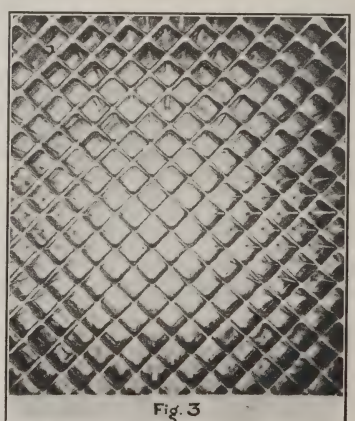
Fig. 2

Although this statement in regard to heat dissipation is not by any means evident, and is in fact entirely contradicted by the heavy curve in figure four, which covers the relation between cooling surface and the size of the air passage on a given radiator, it has nevertheless been established in wind-tunnel tests and is accounted for by the assumption that the air tends to bank up in front of very small tubes rather than flow through, so that the cooling capacity probably varies in accordance with the dotted curve of Fig. 4 rather than directly as the cooling surface. Experiments on very small air passages in this connection have not been extensive, and there is no reason, except as matters of scientific interest, why they hould be; for it has been definitely proved that the resistance tends to increase at a greater rate than the cooling capacity, as the size of the air passage is reduced.

As to the thickness of the cooling section, ribbon type radiators can be obtained in various depths from two and a half inches to five inches. The thickness of the metal in the cooling section may vary anywhere from three thousandths of an inch to five thousandths; but the former thickness has been found too thin in actual use because of two things: first, its inherent weakness, and second, the fact that fine particles of dirt are often rolled into the metal, whose thinness allows this dirt to go all the way through and form leaks as soon as it works out. Metal four thousandths of an inch thick gives satisfactory results, and is therefore recommended.



The thickness of the water passages varies from fifty-five thousandths to eight hundredths of an inch, according to the maker of the radiator. Consideration of this, however, will not be taken in this article.

In addition to the types mentioned above, a type in use by the British (illustrated in Fig. 5), which presents several good points, is on the market. Its core or cooling section consists of an assemblage of round tubes with expanded hexagonal ends, which make the tubes assemblable and prevent the round portions from coming into contact, thus forming the water passages. An exceptionally sturdy construction, in which the soldered joints are all very ample and evenly distributed, this type has given great satisfaction in service. Its ability to cool, however, is not very great and its head resistance is rather high.

Having now touched upon the general types in present day use, with a few recommendations, we may turn to the methods of manufacture.

The stamping or rolling machines are practically automatic, requiring attendance only for the sake of keeping up a fresh supply of metal ribbon and removing the sections as they are cut off. Both ribbons for each small section, containing one water passage, are usually fed through at the same time, and in some cases the sides of one ribbon are cut and automatically folded over corresponding places on the other ribbon, thus locking the two together. Where this is done, individual soldering together of the two sides of each water tube is unnecessary; and no soldering is done until all the small sections are assembled into the complete cooling section.

In any case, the latter is assembled, clamped in a frame of the size and shape of the cooling section, and the whole is dipped on each side in an acid bath, and then in a shallow pool of solder, which is contained in a cast iron dipping vat.

Fig. 3

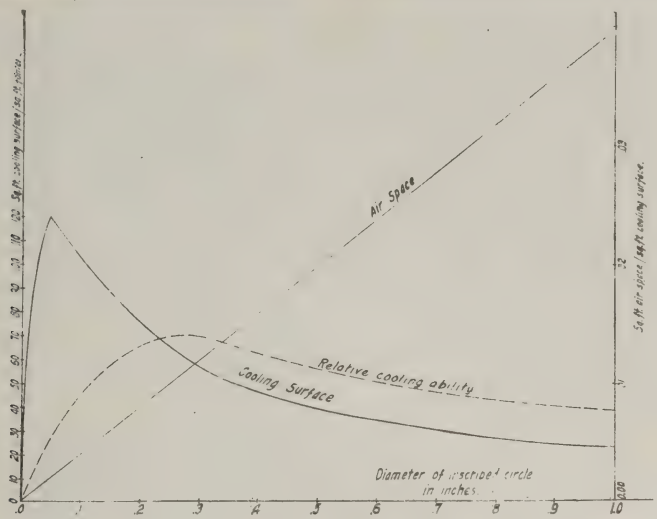


FIG.-4.

After each dip the core is lifted and shaken up and down several times in order to remove all surplus solder. It is then removed from its frame and the ends of the water passages are spread open by means of a small steel wedge. The water headers, or upper and lower tanks are now put in position and tacked on by several small beads of solder, whereupon their location is checked and they are finally soldered on.

In the case of the British or round tube type, the tubes are usually extruded and cut, whereupon the ends are bulged into the hexagonal shape; and the tubes are assembled together. From this point on the construction of the radiator follows the same routine as does the ribbon type.

Design in General

Although a good deal of theoretical discussion must go hand in hand with a full understanding of why to design a radiator for a certain aeroplane in a certain way, as much of this as possible will be set aside, and in this chapter an effort will be made to establish a few general tendencies which should be followed.

Foremost of these is the admonition, DO NOT BE FOOLED BY APPEARANCES. As an example of what is meant by this recommendation, consider

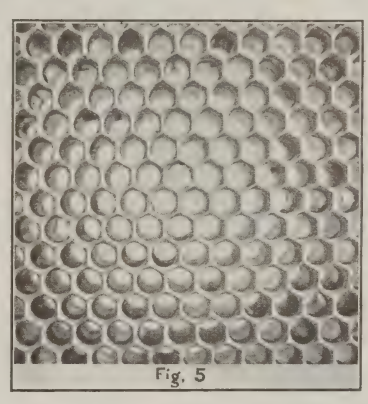

Fig. 5

the nose radiator (Fig. 6). The radiator has, as far as appearances are concerned withdrawn itself from the air into the aeroplane; it does not project into the air stream; it seems to permit of an approximate streamlining of the fuselage and power plant; and it apparently adds no resistance to the machine. Quite contrary to these appearances, however, its use has added an enormous amount of head resistance and an excessive amount of weight, and has partly destroyed the streamlining of the fuselage.

A somewhat analogous case, that of the wing radiator, must be covered later.

An important principle, which should be used where possible is to enclose the engine in a streamline housing entirely, excepting such small parts as should be cooled by the air (such as exposed valve springs and stems); then put the radiator by itself in the free air stream. The reason for this is that although the engine will radiate a certain amount of its own heat if exposed to the wind, it will not do it as *efficiently as a radiator, for the latter is designed to do so and should therefore be given the whole task.

Various objections to enclosing the engine will sometimes arise in machines where it is located out between the wings, such as inaccessibility; and in the event that the engine is left entirely or mostly exposed to the air, the best location for the radiator will probably be directly in front of the engine. If the machine is a tractor, this location will expose the radiator to the high air speed of the slipstream; but, although the radiator would be somewhat more * efficient if located outside of the slip stream, an attempt to locate it there will undoubtedly lead to very long piping and other objectionable installation troubles.

Good practice is to design the radiator in the form of a rectangle, without any tendency toward irregularities in its outline or cooling section. There is at present too great a leaning toward shaping the radiator to fit around the end of the crank case; and this tendency leads to intricate constructional work, greatly weakened radiators and, in many cases, obstructed water flow. Fig. 7, a typical nose radiator, is an excellent example of this kind of design.

Fig. 8 is a good example of a rectangular radiator, which has been designed to offer as little obstruction as possible to the pilot's view. This extreme condition of great height and small width, however, should be avoided and a condition of width slightly greater than height adhered to as closely as possible, although no very great differences in the size of the radiator required for a given job will result from

*The use of the word "Efficient" is merely a convenience. A radiator has no true efficiency, but an analogous term, the "Figure of Merit," can be applied. It is the ratio of the power dissipated by the radiator to the power absorbed in sustaining it in flight.

Fig. 6

different proportions. Appearance alone in this regard is a large factor.

Much trouble has been experienced in the past in estimating the size of radiator required and allowing for it in the general preliminary design of the aeroplane. But the resultant difficulties have confined themselves largely to machines designed for nose radiators; the size and shape of the cowling and nose have in many instances been determined on paper, for a radiator of a certain size, only to result in finding that a larger or smaller radiator must be installed in actual use. There has then followed, of necessity, a general redesigning of the nose and cowling in accordance with the new radiator, which in turn has to be estimated before it can be installed and tried out. With the free air radiator, however, limitations as to size and shape are much wider.

A method of design based on an empirical formula established in the wind tunnel and checked by practice is covered by Fig. 9. Naturally it cannot automatically cover all variations arising from different types of engines and conditions of installation; and it is therefore intended for use only in determining the first trial installation.

The following procedure in using this method should be followed:

Lay a straight-edge between the horsepower and the air-speed, and from the intersection of the straight-edge with the reference line project to the curve and take the reading at the top or bottom. The frontal area of the radiator is then to be taken as

$X \times K_1 \times K_2 \times K_3 \times K_4$ square inches.

Where

X = reading
K_1 = radiator constant
K_2 = radiator position constant
K_3 = engine installation constant
K_4 = engine constant

Fig. 8

and these constants are to be determined as follows:

K_1 is to be taken as .68 sq. in. if a five inch core is to be used and as .82 sq. in. if a four inch core is to be used. (For obvious reasons the constants for different makes of radiators cannot be given, but these values may be taken as applying roughly to the types previously described and recommended.)

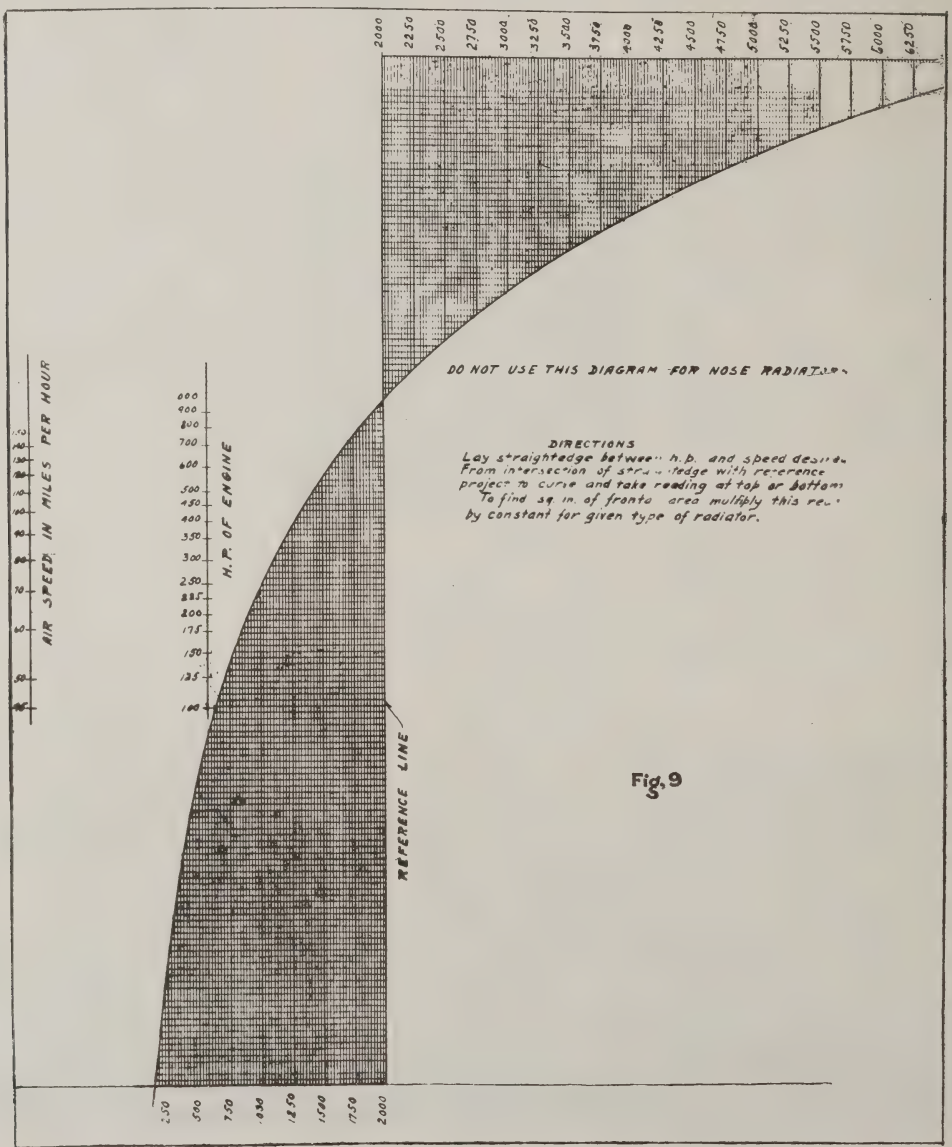

Fig. 9

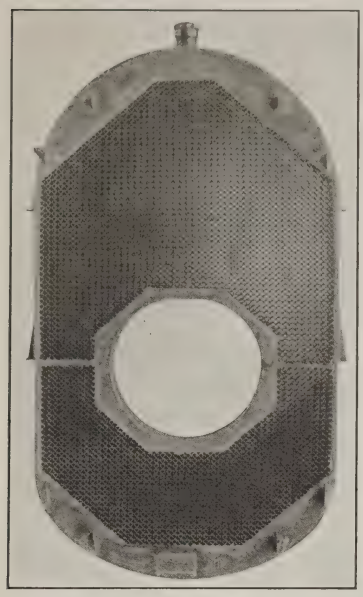

Fig. 7

$K_2 = 1$ if the radiator is to be placed in front of the engine, but should be taken as .9 if the radiator has no obstruction behind.

$K_3 = 1.00$ if engine is exposed

$K_3 = 1.05$ if engine is exposed, but has monoblock cylinder assemblies.

$K_3 = 1.10$ if engine is to be housed in and

$K_4 = \frac{Q}{P} \times .0284.$

Where Q = B.t.u. per minute removed by jacket water in laboratory test

P = Corresponding brake horsepower of engine.

If information leading to the determination is not available, K_4 is to be taken as unity.

Then, having determined upon the trial size, install it in the machine, and determine the following in best climb:

Radiator inlet temperature = T_1

Radiator outlet temperature = T_o

Air temperature = T_a

Then, where

S = correct size of radiator

s = size used in trial

D = desired difference in degrees between air temperature and radiator inlet temperature (usually about 100).

$$S = s\frac{T_1 + T_o - 2T_a}{2D - T_1 + T_o}$$

The derivation of this formula will be covered in a later chapter.

If for any reason the trial radiator is so small that the water temperature reaches the boiling point, the test will be practically valueless unles the amount of steam forced is very small indeed. The formation of steam and its rejection into the air will do away with a great deal of heat, which, of course, would be automatically credited to the radiator in the calculations.

For flying boats and seaplanes intended for training purposes, where a great deal of taxi-ing is done, the size of the radiator should be increased by twelve percent above that determined from the diagram, and the value of "D" should be taken as 90 instead of 100.

In medium size radiators—in the neighborhood of three or four hundred square inches of frontal area—the addition of a small projecting lip extending around the cooling sections may reduce the required size of the radiator by as much as eight percent, but its addition is not recommended unless a special effort must be made to reduce weight or size, as an increase in head resistance which more than offsets the saving in weight is entailed in its use. On small, very narrow radiators, designed to offer little obstruction to view, however, it should be brought into use, as the tendency for the air to slip off the face is very great.

An increase in the heat dissipation and a consequent decrease in the size of radiator required can also be obtained by turning the radiator out of its normal position, the maximum increase in cooling, about twenty percent, coming at about thirty-three degrees away from the normal; but the increase in resistance is so great that this procedure is in no case recommended.

We may now turn to the design of the upper water tank, and in so doing immediately have to determine its exact function. Is it intended merely as a distributor, or should it be a reserve water tank, containing enough water to allow for evaporation? Several considerations affect the answer to this question; but, undoubtedly, on small machines where complication is to be avoided and which are not intended for long flights, the upper tank should serve both as a distributor and as a carrier of reserve water. On large machines intended for flights of very long duration, it should act simply as a distributor or header, and the reserve water

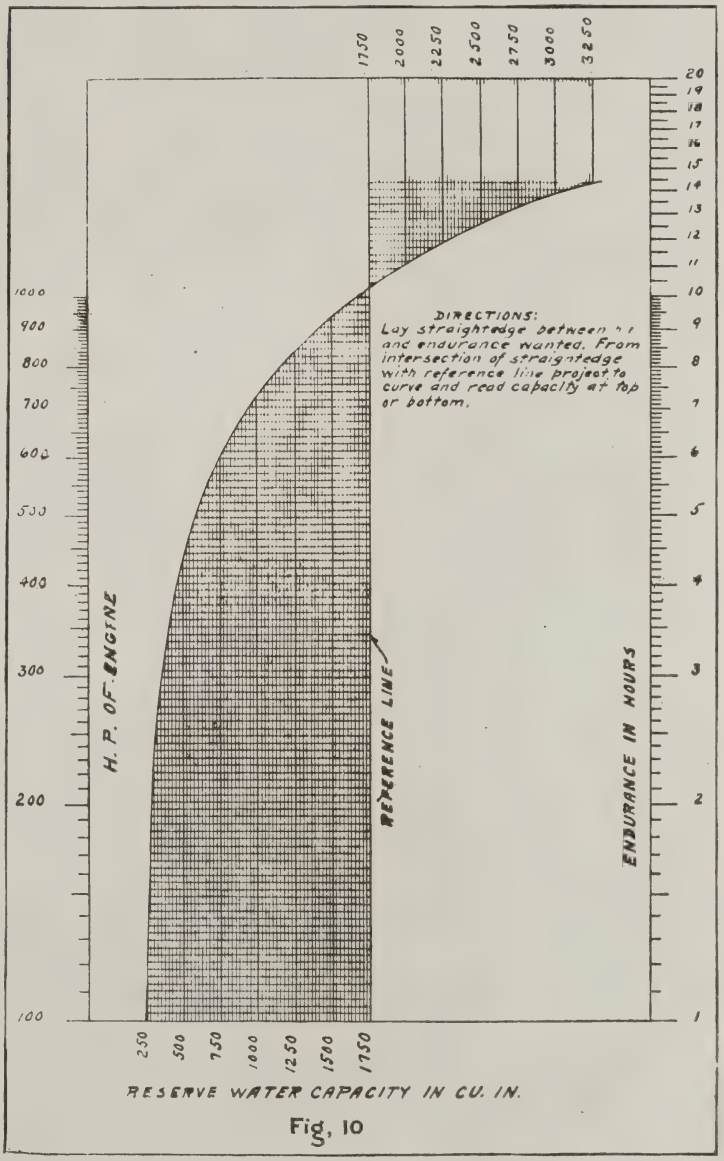

Fig. 10

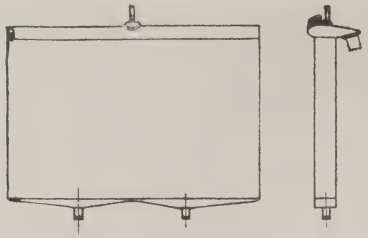

Fig.11

should be removed from the wind and placed elsewhere.

In either case, it is needless to say that the upper tank or header should be streamlined as well as possible.

Fig. 10 covers a method of determining the amount of reserve water, and is based on the British formula:

$$\text{Gallons} = \frac{\text{h.p. x (endurance in hours)}}{1600}$$

which is entirely empirical and is not believed to be final by any means. Its use, however, has given entirely satisfactory results.

There are various opinions concerning the location of the separate reserve water tank, one of these being that it should be carried below the engines and operated by a hand pump. The fallacial reason for this opinion is that if the cooling system leaks the reserve water will not run out. But the absurdity is only too apparent when it is remembered that it will be necessary to pump in the reserve water as soon as a leak occurs. It does not seem feasible to make provision against leakage, as no limit to the amount of extra water can be determined.

An excellent place for the reserve water tank is in the wing, but this location should not be adopted on a machine which is apt to encounter freezing temperatures at a time of the year when it is not desired to carry a non-freezing solution.

The lower header should act entirely as a collector; and should therefore be made as small as possible and on the general lines of that shown in Fig. 11.

Before turning entirely from the consideration of the size of the radiator, a special case must be brought to mind—that of the twin-engined dirigible. This type of craft is very often purposely flown with only one of its two engines in operation; and if the cooling systems are entirely separate, each radiator must of necessity be large enough to cool one engine operating alone; and it should be designed for the speed at which the ship will fly when only one engine is in operation, and should be tested under these conditions. But an especially good installation (Fig. 12) which obviates the use of these larger radiators can be made if the cooling systems of the two engines can be so arranged as to be connected in series at will (assuming that the water pump of each engine is of such a construction as will allow water to pass when it is idle). The radiator of the engine which is not in use is thus made available for furnishing the additional cooling required by the engine which is in operation; the idle engine is kept warm, and in the case of very cold weather the water in the cooling system of the idle engine is kept from freezing. In connection with such an installation, the importance of using shutters or of making the radiators retractable cannot be overestimated.

A Consideration of D

In order to establish the formula $S = s \times \frac{T_1 + T_o - 2T_a}{2D - T_1 + T_o}$ a consideration of what it is based on must be made. It need not be stated that the heat dissipated by a radiator is proportional to the difference between the average radiator temperature and the average air temperature, the former being the mean value of the inlet and outlet water temperatures, and the latter being the mean value of the entering and leaving air temperatures. The temperature of the leaving air, however, may be set aside from consideration for practical purposes because of the general difficulty of determining it, and because the error involved in leaving it out is smaller by far than the probable errors involved in taking the remaining readings. Then, for practical purposes we may take the cooling power of the radiator as being proportional to the difference between the mean radiator temperature and the air temperature; and this difference will hereafter be called the *mean difference*.

Now consider a radiator, of size s, which has been tested in flight, the following conditions having prevailed during this test:

T_1 = radiator inlet temperature
T_o = radiator outlet temperature
T_a = air temperature

Now let m = the mean difference

$$m = \frac{T_1 + T_o}{2} - T_a$$

Now suppose T_1 proved the radiator to be of incorrect size, and it is desired to find the correct size. To do this let

T'_1 = New inlet temperature
T'_o = New outlet temperature
m' = New mean difference
D = Desired $T'_1 - T_a$
S = New size.

Then

$$S = s\frac{m}{m'}$$

$$m' = \frac{T'_1 + {}_1T'_o}{2} - T_a$$

$$D = T'_1 - T_a$$

$$T'_1 = D' + T_a$$

$$T'_o = T_1 - (T_1 - T_o)$$

$$= D + T_a - T_1 + T_o$$

and

$$m' = \frac{D + T_a + D + T_a - T_1 + T_o}{2} - T_a$$

$$= \frac{2D - T_1 + T_o}{2}$$

$$\text{Therefore } \frac{m}{m'} = \frac{\frac{T_1 + T_o - 2T_a}{2}}{\frac{2D - T_1 + T_o}{2}}$$

$$= \frac{T_1 + T_o - 2T_a}{2D - T_1 + T_o}$$

and

$$S = s \times \frac{T_1 + T_o - 2T_a}{2D - T_1 + T_o}$$

Having now established this formula, some consideration should be given to the assigning of values to D; and in so doing it should be borne in mind that although

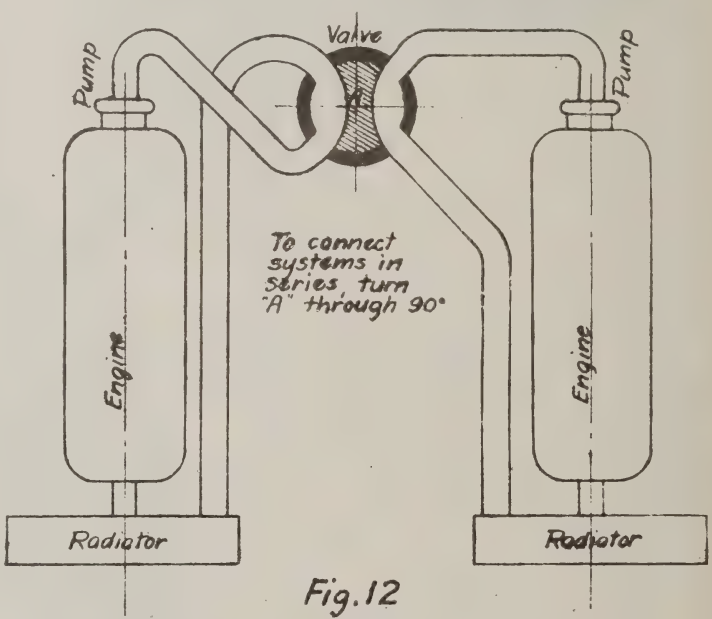

Fig.12

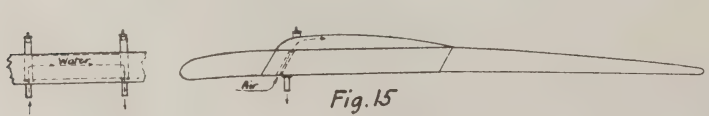

Fig.15

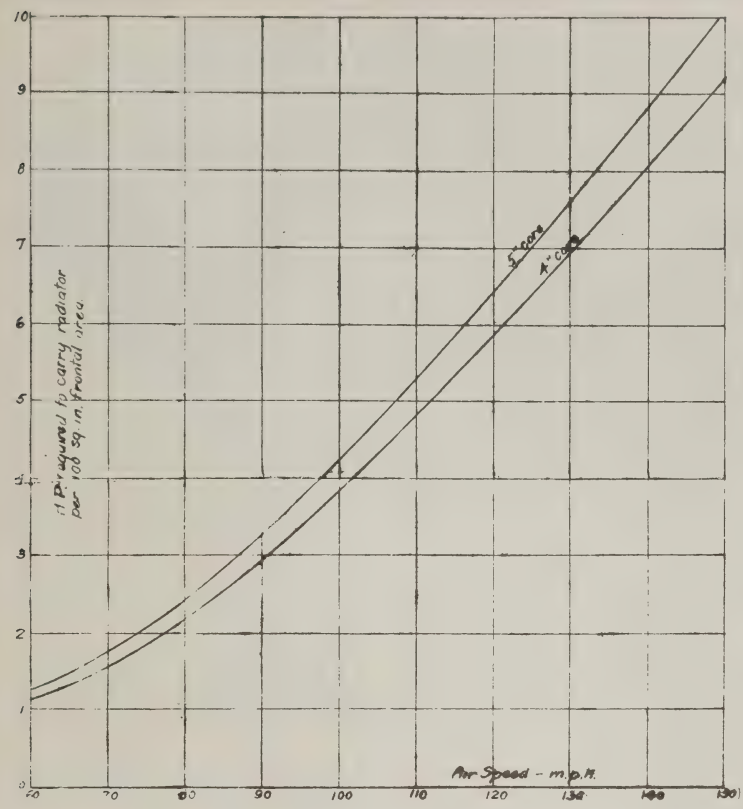

Fig. 14

the size of the radiator does not vary directly as the air temperature (but varies inversely as the mean difference), the temperature of the water in any given installation does very directly as the air temperature. Thus an increase of x degrees in the temperature of the air will give an increase of x degrees in the temperature of the water.

Therefore, to D should be assigned such a value as will not allow the water temperature to go above a desired maximum in best climb at the highest air temperature to be encountered.

A consideration of the effects of altitude on water temperatures in this connection is furthermore necessary; and the following may be taken, in general, as being very nearly true: The density of the air decreases with altitude, the power of the engine varies as the density of the air, but the cooling power of the radiator also varies as the density of the air. Therefore, the only consideration affecting the water temperature, or size of radiator required, is the air temperature (assuming that the percentage of throttle opening on the engine does not change).

The value of D should be based on the average highest air temperature at the ground which will be encountered, and it will be fair to assign a value of one hundred and ninety degrees to the highest desired water temperature. Thus, assuming the average highest air temperature to be ninety degrees D will have a value of one hundred. But although D, in this case, is to be based on the ground temperature, *in all tests the air temperature should be taken* in flight, as it cannot be counted upon as varying in any definite way with altitude. And in all cases the engine should be thoroughly warmed up before taking off.

In the special case of a machine which is to make certain definite trips (such as mail carrying), and can make these in general at an altitude above 5,000 feet, it will be quite possible to assign a value to D as high as one hundred and fifteen.

There is another element which affects the size of the radiator to be used and the value of D, and that is the fact that certain types of engines, due to inherent defects in design, develop more power at lower temperatures than others. If it is noted from the power curve of the engine that it will develop more power at a low temperature, it will, of course, be necessary to determine whether the accompanying increase in size of the radiator will or will not offset the actual gain in the power of the engine. In order to facilitate decisions in this regard the following table, giving a good average relation between values of D and the size of the radiator (given in percent of that *determined from the chart, Fig. 9) is given:

D		Size in percent of that *determined by the chart, Fig. 9.
100	:	100
90	:	112
80	:	127
70	:	148
60	:	175
50	:	216

Fig. 13.

* The size "determined from the chart" is to be taken as the reading taken on the chart plus times the four constants.

In connection with this table the curves, Fig. 14, are intended for use, and may be considered to give fair values of the power required to carry the radiator. Thus, if it is found that by operating the engine at a hundred and sixty degrees instead of at a hundred and ninety degrees, the power will be increased by x horsepower, we assign D a value of 70 and find that the size of the radiator will increase forty-eight percent. We determine from the design chart, Fig. 9, how many square inches of frontal area are entailed by this additional forty-eight percent and refer them to Fig. 14. We then find that an additional y horsepower will be required to carry the radiator, and a direct comparison between x and y can be made.

It is to be noted, however, that if the machine will probably operate at great altitudes there will be no objection to giving D its usual value, as most of the flying is to be done at a considerably lower temperature than that obtaining at the ground and the engine will probably be running at the desired low temperature. In this connection a drop in temperature of 3½ degrees per thousand feet may be expected, but this should never be counted upon in assigning a value of more than a hundred and fifteen to D, as there will probably be many instances where the air temperature will vary irregularly with altitude.

The Fallacy of the Nose Radiator

Practice is slowly abandoning the nose radiator, but all too slowly; and it is believed that in many cases the abandonment has been made solely because of its excess weight and cumbersome construction, with considerable doubt still existing as to whether, taking everything into consideration, it should really and finally become a thing of the past or not. Undoubtedly, it makes a very neat installation, becoming an integral part of the fuselage, as far as appearances are concerned and apparently offering no additional head resistance to the aeroplane. So there are still its advocates.

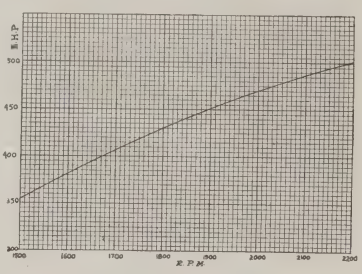
The argument that a radiator operating in a slow air flow does its work with a smaller amount of energy being spent on it is often brought forward in its favor; and is quite correct as applied to the nose radiator by itself. It does operate in a slow air flow, and is undoubtedly efficient by itself. But the argument should not confine itself to the radiator alone, but to the conditions resultant from its installation, for the air speed is slow because of the enormous amount of resistance which it encounters behind the radiator — in swirling around the engine, pipes, wires and braces, and in finally finding its way out through some opening which is entirely too small. Furthermore, allowing the air to flow into the nose of the machine destroys the effectiveness of its streamlining. The result is that the head resistance due to the radiator is very much greater when the radiator is in the nose than it would be if the radiator were out in the free air stream; and because of the small amount of air flowing through it, it has to be unusually large and heavy.

It has been found that when the nose radiator is partly covered the speed of the machine will increase. This fact, and the instance of a British machine from which the nose radiator was removed, are excellent practical examples of the case against this kind of an installation.

On the machine in question an increase of fourteen percent in rate of climb at

(*Continued on page* 1286)

NAPIER "LION" IN AERO ENGINE



By G. DOUGLAS WARDROP, M. S. A. E., A. S. M. E.

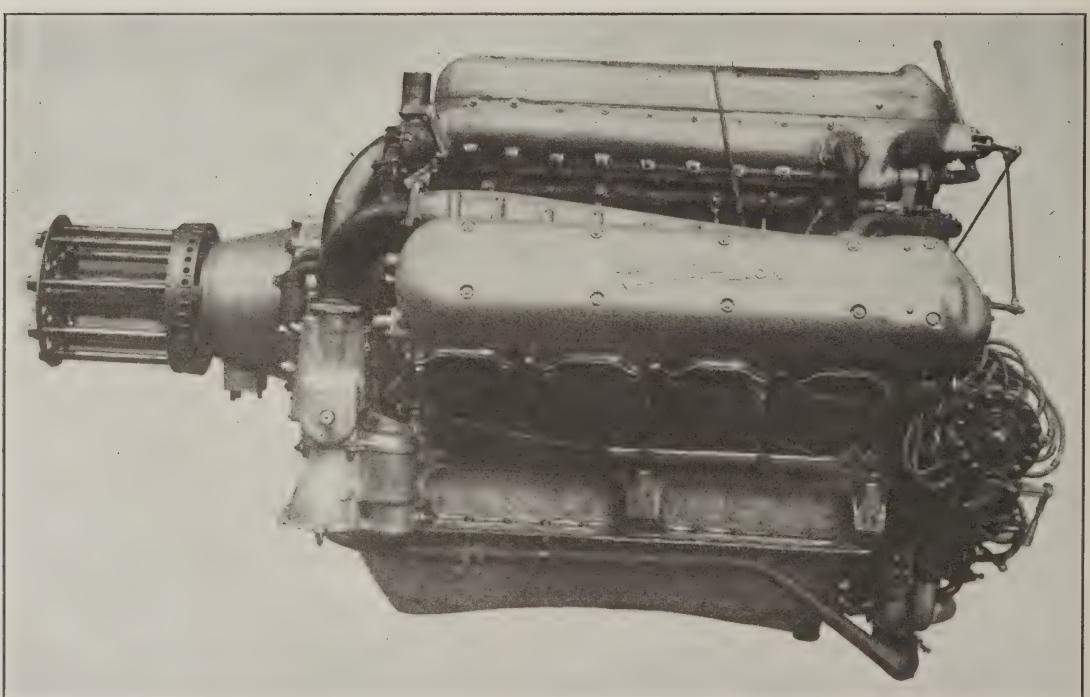
THE Napier "Lion" 12-cylinder aero engine, manufactured by D. Napier & Sons, Ltd., of England, attracted international interest recently because of the unofficial record which it enabled Capt. Lang of the British Air Force to make when he reached an altitude of 30,500 feet.

The engine has 12 cylinders arranged in three blocks of four cylinders, the angle between each block being 60°. The cylinder bore is 5½" and the stroke 5⅛".

The Cylinders are made from steel forgings and are machined all over. The four cylinders in each block are secured to the crankcase by studs and nuts and to an aluminum head casting which contains the inlet and exhaust passages and the valves and valve mechanism. The cylinders are fitted with steel water jackets and two ignition plugs. There are two inlet and two exhaust valves in each cylinder. The valves are each fitted with two coil springs and a special friction locked tappet head and are operated direct by two camshafts which are carried in gunmetal bearings mounted on the head casting of each block. The camshafts are driven through bevel gearing by vertical shafts from the crankshaft at the rear end of the engine.

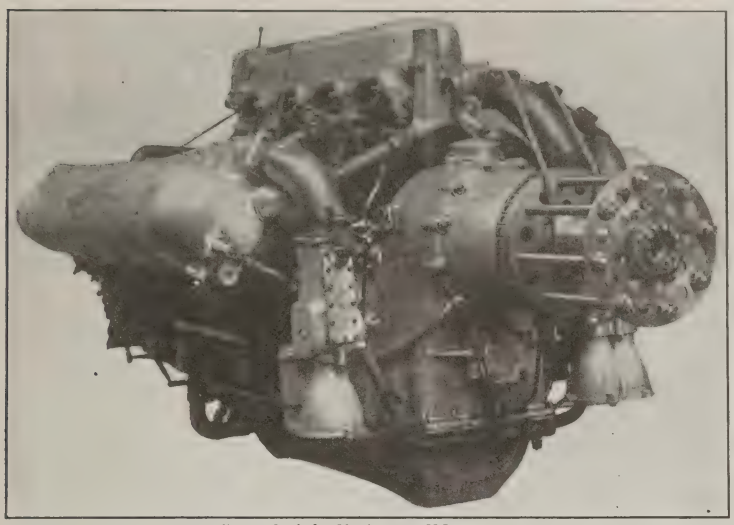
The Crankcase is an aluminum casting and is carried in the fuselage by six arms, three on either side. The front end encloses the propeller drive reduction gear and carries the airscrew shaft cover, airscrew shaft and bearing. The casting for the camshaft water and oil pumps and magneto drives is bolted to the rear end of the crankcase. The roller and plain bearings of the crankshaft are carried on the cross walls of the casting and are fitted with steel caps and studs. A large breather is mounted on the reduction gear casing.

Brake H.P. curve of the Napier "Lion" aero engine



The Oil Sump of pressed aluminum, to which a stiffening plate is riveted, is bolted to the bottom flange of the crankcase. The sides and ends slope inwards and the bottom downwards from the middle towards the ends. Two steel suction pipes are fitted inside the sump, one leading to either end and connected to the suction oil pumps. The steel oil pipe carrying oil to the front end of the crankshaft also passes through inside the pump.

The Crankshaft is very rigid and is machined from a solid steel forging. It has four throws all in one plane. The crankpin and journals which are of large diameter are bored out and fitted with end plates held in position by bolts passing through the holes in the shaft. Holes are drilled in the webs connecting the pins and journals to the ends of the shaft. The shaft is carried in five substantial roller bearings and one plain bearing at the front end. The crankshaft reduction gear is fitted at the front end of the shaft and is carried on a taper and two keys and held in position by a nut.



The Airscrew Shaft, which rotates in a clockwise direction, is carried on two roller bearings and is fitted with a large double thrust ball bearing which permits of the engine being used on either pusher or tractor machines. The reduction gear wheel of spur tooth type, is bolted and spigotted on to a flange solid with the shaft. The airscrew shaft and gear can be withdrawn from the crankcase complete with the cover. The reduction between the crank and airscrew shaft is 1.52 to 1. The propeller boss is made to Air Board Standard No. 4.

The Pistons are of aluminum alloy with large diameter hollow gudgeon pins fitted into steel bushes cast integral with the piston. There are two gas and two scraper rings.

The Connecting Rods are machined from high grade steel stampings. The big end of the master rod—which is

The Napier "Lion" 450 H.P. Aero Engine. This power plant was used by Capt. Lang in establishing the world's altitude record of 30,500 feet

Propeller end of the Napier 450 H.P. aero engine

coupled to the pistons on the vertical block of cylinders—is lined with white metal. There are four lugs on the master rod, two on either side, for the two short auxiliary rods. The gudgeon pin ends of all the rods and the anchor pin ends of the auxiliary rods are bushed. Pipes for carrying oil to the gudgeon pins are fitted. All the working surfaces are pressure lubricated.

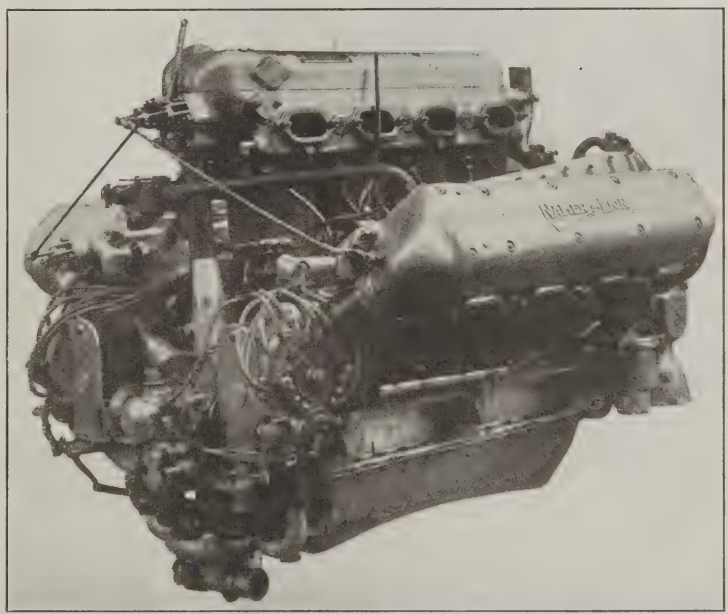
Auxiliary Drives. The magnetos, water and oil pumps are driven through bevels mounted on a short auxiliary shaft carried on the rear end cover. The front end of the shaft engages in slots on the crankshaft and is driven at crankshaft speed.

The Water Pump is mounted vertically under the rear end cover and runs at engine speed. The pump delivers water through three outlets to the rear end of the jacket on each cylinder block. A white metal packed stuffing box and greaser is fitted.

Oil Pumps. There are two suction and one pressure spur gear type oil pumps fitted at the rear end of the cover casting. The suction pumps are connected to the ends of the oil sump. The pressure pump delivers oil from the supply tank to both ends of the crankshaft. All the pumps run at half engine speed and are driven through bevels and spiral gears from the auxiliary shaft. The capacity of either suction pump is greater than that of the pressure pump. An oil filler is fitted between the pressure pump and the supply tank.

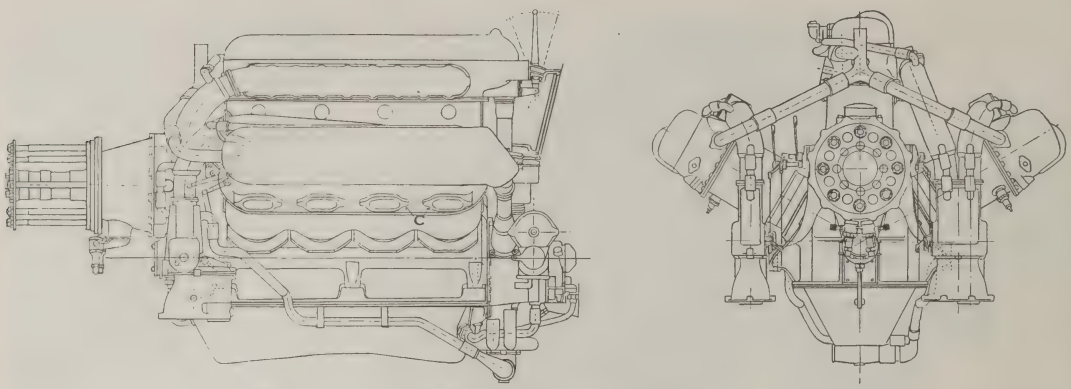
Magnetos and Ignition. The two special 12-cylinder dual ignition magnetos (B. T. H. AV12, L & S) are mounted on transverse platforms on the rear end cover and are secured by set screws. The magnetos rotate anti-clockwise and are driven at two-thirds engine speed through bevels from the auxiliary shaft. They are fitted with special rotors to facilitate starting up by hand; the advance and retard levers are interconnected through links and bell crank levers mounted on the rear end cover. The ignition cables are carried in tubes mounted on the crankcase.

A Tachometer Drive is mounted on the casting carrying the drive shaft for the vertical cylinders, rotates at one-quarter engine speed and is fitted with a standard Air Board end connection.



Carbureters. One double (N. D.) and one single (N. S.) carbureter is fitted on the engine. The double carbureter is mounted on the L. H. side and supplies the L. H. and vertical cylinder blocks. The single carbureter is mounted on and supplies the R. H. block. They are connected through water jacketted steel pipes to the induction manifold on the cylinder head castings. The carbureter bodies are of aluminum in two halves and are water jacketted. Both carbureters are fitted with altitude control cocks which are interconnected through levers to the throttle levers at the pilot's cockpit. The carbureter control shafts are carried in brackets on the crankcase. The carbureters are stayed to the crankcase to prevent vibration. Under running conditions the pipes and cock fitted at the rear ends of the induction manifolds act as an equalizing system for the three cylinder blocks.

Lubrication. All the connecting rod big ends, gudgeon pins and crankshaft plain bearing are pressure lubricated. Branch pipes from the pressure pump convey oil under pressure to the camshafts and bearings. The oil escaping from the ends of the bearings lubricates the valve tappets and is drained away at the ends of the head casting into the sump and returned by the suction pumps to the supply tank. The reduction gears are lubricated by oil squirted on to the teeth through a pipe connected to the crankshaft oil system. An adjustable leak pressure relief valve and a pressure gauge connection are fitted in the pressure system.



Gas Starter. The engine is started by pumping an explosive air petrol gas mixture into the cylinders; the mixture is then ignited by means of a hand starting magneto operating through the special rotors on the engine magnetos. The gas starter comprises a hand operated air pump, petrol vaporizer, a distributing or equalizing cock with pipes, and a system of levers mounted on the cylinder head castings for opening the valves by hand.

The engine, complete with propeller boss, carbureters, induction pipes, etc., weighs 850 lbs. approx:

First Lieut. John R. Castleman, Air Service pilot, 99th Aero Squadron. For extraordinary heroism in action near Romagne, France, October 5, 1918. In spite of being attacked by seven enemy planes, type Fokker, and later by five, type Pfalz, Lieut. Castleman successfully accomplished a photographic mission 6 kilometers behind the German lines, without protection, and also destroyed two of the enemy planes. Home address, F. I. Castleman, brother, 128 Rochelle Avenue, Wissahickon, Philadelphia, Pa.

First Lieut. John Y. Stokes, Jr., Air Service, 20th Aero Squadron. For extraordinary heroism in action near Etain, France, September 16, 1918. After their own formation had been broken up, Lieut. Stokes and his pilot voluntarily continued on their bombing mission with planes from another squadron. Although their plane was thrown out of control by antiaircraft fire, they proceeded to their objective and dropped their bombs. Their motor then died completely, and they were attacked by an enemy combat plane, but they fought off the attacking machine and reached the allied lines, where their plane crashed in a forest. Home address, John Y. Stokes, father, West Market, Reedsville, N. C.

Second Lieut. Edw. M. Morris, pilot (Air Service). For extraordinary heroism in action near Landres-et-St. Georges, France, October 30, 1918. Unable to complete a photographic mission, owing to motor trouble, Lieut. Morris, with his observer, made a reconnaissance behind the German lines. They dispersed a battalion of enemy troops, and although twice attacked by enemy patrols, drove them off and each case brought down one enemy plane. They remained in the air until their motor failed completely. Home address, Mrs. Rose Morris, 109 West One Hundred and Twenty-ninth Street, New York, N. Y.

First Lieut. Flynn L. A. Andrew, observer (Air Service). For extraordinary heroism in action near Landres-et-St. Georges, France, October 30, 1918. Unable to complete a photographic mission, owing to motor trouble, Lieut. Andrew, with his pilot, made a reconnaissance behind the German lines. They dispersed a battalion of enemy troops, and although twice attacked by enemy patrols, drove them off and in each case brought down one enemy plane. They remained in the air until their motor failed completely. Home address, Mr. Wm. H. Andrew, 1441 Pennsylvania Avenue, Denver, Colo.

Capt. Clearton H. Reynolds, pilot (Air Service). For extraordinary heroism in action near Romagne, France, October 9, 1918. Although weather conditions made flying exceedingly dangerous, Capt. Reynolds, with his observer, started on a mission to determine the position of the front-line troops of the division to which his squadron was attached. Flying at an altitude of 20 meters, they encountered and defeated three enemy patrols, gathered and deliverd to division headquarters very valuable information. Home address, Mrs. Lena B. Reynolds, mother, 33 North Seventeenth Street, East Orange, N. J.

First Lieut. Britton Polley, observer (Air Service). For extraordinary heroism in action near Romagne, France, October 9, 1918. Lieut. Polley was assigned to a mission to find line troops of the division to which his squadron was attached. Weather conditions made flying almost impossible, a second plane, assigned to the mission returning on that account. Flying at an altitude of 25 meters over enemy lines, he encountered and defeated three enmy patrols, gathring and delivring to his division headquarters, most valuable information. Home address, J. W. E. Polley, father, 440 East One Hundred and Sixty-sixth Street, New York, N. Y.

Second Lieut. Frank Luke, Jr., deceased, Air Service, 27th Aero Squadron. For the following act of extraordinary heroism in action near Etain, France, September 18, 1918, Lieut. Luke is awarded a bar to be worn with the distinguished-service cross awarded him November 8, 1918. Immediately after destroying two enemy observation balloons, Lieut. Luke was attacked by a large formation of German planes, Fokker type. He turned to attack two, which were directly behind him, and shot them down. Sighting an enemy biplane, although his gasoline was nearly gone, he attacked and destroyed this machine also. Next of kin, Frank Luke, 2200 West Monroe Street, Phoenix, Ariz.

Post Office Department Asks for Bids to Modify D. H. 4's

The Post Office Department has advertised for bids for the reconstruction and modification of the DeHaviland aeroplanes turned over to the Postal Service by the War Department. Sealed proposals for this work will be opened on February 26 at the Department in Washington.

The bids requested call for changing and modifying 12 DeHaviland 4 aeroplanes, and as many more up to 60, in lots of 12, as the Postmaster-General may direct. The changes to be made may be determined by inspecting a sample plane at the mail aviation field at Belmont Park, Queens, Long Island, New York, which may be surveyed and compared with the D. H. 4 battle planes, a specimen of which may also be found at the aviation field.

The changes comprehend the following, and such other changes as may be shown in said remodeled D. H. 4 plane at Belmont Park aviation field:

1. Pilot cockpit to be moved to rear.
2. Longerons on fuselage to be reinforced with 1/32" steel channels from front engine plate to rear of pilot's cockpit.
3. Longeron splices to be reinforced with steel plates.
4. Upper engine section wire to be increased in size and fittings reinforced with metal straps running diagonally from upper to lower longerons.
5. 1/32" steel reinforcing strip to be replaced on sides of fuselage from lower reinforcing strip to center sections fore and aft wires.
6. Bulkheads to be reinforced with cross bracing.
7. Mail compartment to be finished with 3/16" three-ply veneer and suitable covers and straps.
8. Turtleback to be better streamlined from rear of pilot's cockpit to stabilizer.
9. New cowling to be provided from engine to rear stabilizer.
10. All outer struts to be pinned with bolts.
11. To be fitted with stronger landing gear and same placed forward of old position, as per sample plane.
12. Bracing wires to be installed on elevators and rudders.
13. Stabilizer under brace to be tightened with bolts instead of pins.
14. Fitting at front lower longeron to be strengthened to take load of upper drift wire off wood by making fitting to go around longeron.
15. Rudder to be so arranged as to give plenty leg room.
16. Two pressure gasoline tanks and gravity tank totaling 180 gallons to be installed.
17. Instrument board to be placed as in sample D. H. 4 now at Belmont Park.

Delivery: The time for delivery of work should not be longer than four weeks from date of award for six of the machines, the second lot of six to be delivered within two weeks thereafter.

The Department will deliver the ships to and from factory.

Air Mail for Honduras

New Orleans.—Aeroplane mail service between Honduras, Nicaragua, Salvador and the United States is soon to be established, according to Joaquin Bonilla, Honduras counsel to Manchester, England, who has arrived in New Orleans from Honduras.

Mr. Bonilla said details are now being worked out and it was expected the service would be in operation within the next few months with Tegucigalpa as the main base. Mr. Bonilla is a son of Manuel Bonilla, former President of Honduras.

American Aces Tell Exploits In Washington

Washington, D. C.—Three American aces, Captain "Eddie" Rickenbacker with twenty-six planes credited to him, Lieut. J. O. Donaldson, credited with nine victories, and Captain Douglas Campbell, with seven victories, were the guests of the National Press Club on the night of February 13. Each of the aviators made addresses recounting some of their experiences in France. The story of Lieut. Donaldson, who is a resident of Washington, was the first account of his adventures given in public. Donaldson was captured by the enemy, but succeeded in eluding his captors and making his way with a companion to a German aerodrome. An effort was made to reach the allied lines by aeroplane, and after three hours of "tuning up" in the darkness of a hangar a German officer interrupted them. However, the two aviators made their way to the woods, where they were captured and placed in solitary confinement. A second attempt, this time successful, was made several weeks later, Donaldson being accompanied by four other officers.

Victor Chapman Extolled In Music

New York, N. Y.—The Society of the Friends of Music gave a concert at Aeolian Hall on February 15 in memory of Victor Chapman, one of the first American aviators to give his life for the cause of democracy. The composition rendered was written for the occasion by Charles Martin Loeffler.

Dirigible Endurance Record Broken

Cape May, N. J.—Remaining aloft for 33 hours and 6 minutes under the most unfavorable weather conditions, the naval dirigible C-3 last week established what is claimed to be a world's endurance record for the non-rigid type of balloon.

The C-3, with Ensign Clarence W. Tyndall of New York in command, left its hangar at the naval air station here last Wednesday at 4.35 P. M. Bad weather set in a few hours later and during the cruise up and down the coast rain, high winds, snow and extremely low temperatures were encountered. Early Friday the dirigible developed motor trouble, and at 1.41 o'clock that morning a safe landing was made on the flying field at Cape May.

The C-3 is of the blimp type developed during the war by the British Royal Flying Corps, and is the largest dirigible balloon in the navy's service. Ensign Tyndall was accompanied by two pilots, a radio operator and two mechanicians.

In its first endurance cruise about three weeks ago the C-3 remained aloft for twenty-seven hours and covered a distance of more than 1,000 miles.

Four French Air Mail Lines in Operation

Paris.—The fourth civilian postal air line in France will be in operation soon between Paris and Nice with landings at Lyons and Marseilles, according to the New York *Globe*. The most recently established service, that between Paris and Lille, is more than four times faster than the present train service, taking one hour and forty minutes instead of eight hours, while the two hours and a quarter mail service between Paris and Brussels is proving a great time saver, railway trains sometimes requiring twenty hours for the trip.

The Paris-St. Nazaire line, which has been in operation since August 17 on an average of eighteen days out of every thirty, is expected, as is the case of other services, to run about 80 per cent. of the time with better weather conditions in March and 90 per cent. or better in April and the succeeding summer months.

Mrs. Roosevelt Pays Tribute to Quentin

Paris.—Mrs. Theodore Roosevelt, accompanied by her son, Lieutenant Colonel Theodore Roosevelt, Jr., visited the grave of Lieutenant Quentin Roosevelt, near Fere-en-Tardenois, and laid flowers on the simple monument which marks her son's last resting place. The grave is being carefully tended by the inhabitants of the locality.

While on a patrol with two other machines, he attacked an enemy formation of seven planes (Fokker type) that were protecting a biplace plane. They destroyed the biplace and four of the Fokkers, forcing the remaining three to retire. A bronze oak leaf, for extraordinary heroism in action in the region of Moiry, France, October 23, 1918. He led a formation for the purpose of protecting our bombing planes, the accompanying planes being obliged to return, due to engine trouble. Despite this fact, *Lieut. Patterson* proceeded on the mission alone. He sighted an enemy patrol of nine machines (Fokker type) and attacked them, driving one down.

Wilbur C. Suiter, First Lieutenant, Air Service, Pilot, 135th Aero Squadron. For extraordinary heroism in action near Vilcey-sur-Trey, France, Septembr 12, 1918. He, with *Second Lieut. Guy E. Morse,* Observer, fearlessly volunteered for the perilous mission of locating the enemy's advance unit in the rear of the Hindenburg line. Disregarding the hail of machine-gun fire and bursting anti-aircraft shell, they invaded the enemy territory at a low altitude and accomplished their mission, securing for our staff information of the greatest importance. These two gallant officers at once returned to the lines and undertook another reconnaissance mission, from which they failed to return.

Guy E. Morse, Second Lieutenant, Observer, 135th Aero Squadron. For extraordinary heroism in action near Vilcey-sur-Trey, France, September 12, 1918. He, with *First Lieut. Wilbur C. Suiter,* Pilot, fearlessly volunteered for the perilous mission of locating the enemy's advance unit in the rear of the Hindenburg line. Disregarding the hail of machine-gun fire and bursting anti-aircraft shell, they invaded the enemy's territory at low altitude and accomplished their mission successfully.

First Lieut. Frank Ordiscoll Hunter, Air Service, 130th Aero Pursuit Squadron. For the following act of extraordinary heroism in action near Verneville, France, September 17, 1918: Leading a patrol of three planes, *Lieutenant Hunter* attacked eight enemy machines. He then returned to the flight and succeeded in destroying another and driving off the others. Home address, John H. Hunter, father, 216 East Gaston Street, Savannah, Ga.

First Lieut. Ralph P. Bagby, Field Artillery, observer, 88th Aero Squadron. For extraordinary heroism in action near Tailley, France, November 2, 1918. *Lieutenant Bagby* and First Lieut. Louis G. Bernheimer, pilot, on their own initiative went on a reconnaissance mission, flying 50 kilometers behind the German lines, securing valuable information as to the condition of the bridges across the Meuse River and enemy activity in the back areas and also harassing enemy troops. Home address, R. J. Bagby, father, New Haven, Mo.

Major Smith Ends Transcontinental Flight

San Diego, Cal., February 14.—Completing one of the record flights in aviation history, Major Albert Smith ended his flight across the country and back on February 14. Major Smith began his flight from San Diego to New York on December 4. Although a great many days have elapsed since the start of the flight, most of the time was spent along the Atlantic coast in flights from Long Island to Washington, and long stops prior to the start of the return journey.

On the last day of the flight Major Smith had breakfast at Fort Bliss, Texas, luncheon at Yuma, Arizona, and dinner at San Diego.

French Air Mission Coming

Paris.—A French aviation mission will start for the United States on March 8 to demonstrate the degree of efficiency French aeroplanes have attained. The mission will take with it five of the fastest machines which have been turned out. One of the planes is fitted with a closed cabin for the use of the Americans who have been invited to accompany the mission, which will have five of the noted French aces as pilots for the machines.

Authority and Function of the Director of Air Service

To enable the Director of Air Service to exercise the necessary supervision, control and direction over the Bureau of Aircraft Production and the Division of Military Aeronautics, with which he is charged by direction of the Secretary of War, the following was announced by the Chief of Staff:

The Director of Air Service will carry out the duties of the Chief of the Air Service, as prescribed in Article LXXXI, Army Regulations, 1913. He will exercise, under the direction of the Chief of Staff, full and complete supervision, control, and direction over the Bureau of Aircraft Production and the Division of Military Aeronautics, in all that pertains to administration, supply, instruction, training, and discipline.

General Orders, No. 80, War Department, 1918, have been amended by striking out the words "the Directors of Military Aeronautics,—of Aircraft Production," and substituting the words "The Director of Air Service."

Fourragers

The Director of Military Aeronautics has just been advised by cable from General Pershing, that the 103d, Aero Squadron, formerly the Lafayette Escadrille, is one of the two organizations of the A. E. F. entitled to wear Fourragers awarded by the French government. This organization was awarded the Fourragers in the colors of the Croix de Guerre, having received two citations of the French Orders of the Army. The names of the individuals qualified to wear this decoration will be published shortly.

Military Aeronautics Strength

Figures prepared by the General Staff show that 60 per cent of Total Personnel of the Division of Military Aeronautics was Overseas on February 6th.

Distribution of personnel in United States and overseas at various dates is shown in the following diagram:

Date	*Number*		*Per Cent*	
	In U. S.	Overseas	U. S.	Overseas
Nov. 11.....	79,321	78,786	50	50
Nov. 18.....	80,689	78,973	51	49
Nov. 25.....	84,785	78,361	52	48
Dec. 2.....	84,844	78,061	52	48
Dec. 9.....	889,661	70,040	56	44
Dec. 21.....	81,607	61,245	57	43
Dec. 26.....	77,140	59,917	56	44
Jan. 6.....	67,833	59,584	53	47
Jan. 16.....	51,321	58,854	47	53
Jan. 23.....	46,467	58,133	44	56
Jan. 30.....	41,314	57,527	42	58
Feb. 6.....	37,537	56,299	40	60

Reduction of Personnel

The War Department recently announced that the Air Service Personnel, in Washington, had decreased as follows:

Division	Civilian Personnel Nov. 11	Net reduction Nov. 11- Feb. 7	Per cent decrease Nov. 11- Feb. 7
Aircraft Production..	1,861	579	31

Military Aeronautics. 1,100	313	28
The Total Figures for whole War Department are..... 25,892	6,536	25

Cancelled Aircraft Contracts

The War Department has announced Aircraft Contract Cancellations to the value of contracts cancelled and suspended $469,000,000.

The following is a summary of cancellations and suspensions of contracts to Feb. 7th:

	Value	Per cent of total
Engines and spare parts....	$250,107,551	53
Planes and spare parts.....	163,231,790	35
Chemicals	13,181,285*	3
Balloons and balloon supplies	9,877,356*	2
Instruments and accessories	9,864,238*	2
Fabrics, lumber and metals.	5,954,726*	1
Miscellaneous	16,631,047	4
Total	$468,847,993*	

* Reductions due to revision in cancellations of contracts.

Suspensions of Plane and Engine Contracts

The value of planes and engines delivered during the week ended February 7 was nearly $2,000,000, leaving a balance on order valued at over $10,000.00.

Planes	Balance on order Nov. 11	Suspended Nov. 11 to Feb. 7	PER CENT Suspended	Delivered	Remaining
Service	$124,818,750	$113,968,750	91	8	
Adv. Training.....	12,203,600	9,677,700	79	18	3
Elem. Training	5,400,000	4,187,358	77	23	
Total	$142,422,350	$127,833,808	90	9	
Engines					
Service	$227,010,000	$193,452,000	85	14	
Adv. Training.....	31,377,500	14,926,295	48	27	25
Elem. Training.....	2,864,200	0		93	7
Total	$261,251,700	$208,378,295	80	17	3

331 Liberty Motors Remaining on Order

During the week ended February 7th a total of 189 Liberty motors were delivered, leaving 331 still on order. To date 20,147 have been produced.

The status of contracts on February 7th is shown below:

	Balance on order Nov. 11	Suspended Nov. 11 to Feb. 7	Delivered Nov. 11 to Feb. 7	PER CENT Suspended	Delivered	Remaining
Nordyke-Marmon Co.....	4,548	4,000	548	88	12	
Lincoln Motor Corp.....	13,228	10,500	2,728	79	21	
Packard Motor Car Co.....	7,373	5,600	1,473	76	20	4
General Motors Corp.....	3,430	2,472	927	72	27	1
Ford Motor Co.....	1,947	1,050	897	54	46	
Total	30,526	23,622	6,573	77	22	1

42 De Haviland 4 Planes Remaining on Order

Deliveries of De Haviland 4 planes during the week ended February 7 were 5, leaving 42 still on order. A total of 4,600 exclusive of 204 shipped without engines, have been produced.

The status of contracts on February 7 is shown below:

	Balance on order Nov. 11	Suspended Nov. 11 to Feb. 7	Delivered Nov. 11 to Feb. 7	PER CENT Suspended	Delivered	Remaining
Standard Airc. Corp.	421	360	61	86	14	
Fisher Body Corp.	3,031	2,400	631	79	21	
Dayton Wright Air. Co.....	2,623	1,900	681	72	26	2
Total	6,075	4,660	1,373	77	22	1

7th Aero Squadron

Reporting from France Field, Cristobal, Canal Zone, on January 25, 1919, the Information Officer writes as follows:

"This week a flight was made to San Blas, R. P., in an HSIL flying boat, a distance of 180 miles being covered in aboui 140 minutes. On the trip to San Blas the boat carried four passengers (including pilots) and about 200 pounds of extra equipment. Two of the passengers were Air Service men who are on hunting pass, and in addition will make a hurried survey of conditions in the San Blas territory. The San Blas tribe of Indians is an old race, with many historical traditions. They have never been conquered, and the Panamanian Government is making some effort to educate them and to strengthen their allegiance to the Republic. A peculiarly shy and child-like people, these Indians have many habits of dress and adornment which are interesting. All their women wear nose rings of imitation gold almost from infancy, cover their heads and faces with cheap cotton shawls of elaborate design, wrap their legs tightly with a fabric strip and paint a stripe of varying color on their noses. The chief men are distinguished by circular earrings, also of imitation gold.

New Gas Station

The Panamanian Governor of the Province offered to allow the use of a portion of the Capital Island, Porvenir, for aviation purposes, and to build a gas station there. Co-operating with Navy aviation officers, the commanding officer of France Field plans to visit Porvenir within the next week in a Navy submarine chaser and one of France Field's boats, the U. S. A. David Putnam, and complete arrangements for the establishment of this gasoline station. This base will assist the operation of sea planes from France Field along the entire Atlantic coast of Panama, a distance of approximately 700 miles. The value of establishing gasoline stations of this kind is apparent when it is learned from Navy sources that six Curtiss NC1 flying boats are capable of landing 200 soldiers and equipment at any point along a 700-mile coast line in about three hours' time.

The 64th Balloon Company

Lieut. Col. H. B. S. Burwell, J. M. A., Commanding Officer of Rockwell Field, has commended the Commanding Officer, Arcadia Balloon School, on his co-operation in the Rockwell Field "Flying Circus," as follows:

"It is desired to extend to you my sincere thanks and appreciation for the wonderful way in which you co-operated with us in making the Rockwell Field 'Flying Circus' a success. The presence of the balloon company was one of the principal features of the circus, and the work done by the officers and enlisted men of that command is appreciated by myself and every member of this command.

"In spite of the very unfavorable weather conditions you were able to carry out your end of the program to the complete satisfaction of everyone present. It was a great pleasure to have you here as our guests, and our one regret is that we were not able to show how fully we appreciated the great trouble that you went to in bringing down the balloon company and equipment.

"The circus was a financial success and netted a substantial sum which will be used for the benefit of the enlisted men. Should you decide to stage a similar show at Arcadia you can rest assured that we will do everything in our power to co-operate with you in the way of furnishing aeroplanes and pilots and any other equipment at our command."

Lieut. Col. Mygatt conveyed the message to the 64th Balloon Company with the following indorsement:

"The work of the 64th Balloon Company, during the Flying Circus at Rockwell Field, is greatly appreciated by the Commanding Officer at that station. He states that the presence of the Balloon Company was one of the principal features of the circus, and the work done by the officers and enlisted men of this company was appreciated by himself and every member of his command. The handling of the balloon was excellent and the parachute jumps were perfect. The discipline and appearance of the company, in spite of the inclement weather and excessive work because of it, was all that could be desired. The Commanding Officer takes this opportunity to thank the officers and men of the 64th Balloon Company, and the officers attached to it, for their excellent work. A thorough performance of duty such as this reflects great credit upon the Balloon Service."

Firing Commands by Radio Telephone

A Field Artillery Brigade in action, with its Artillery Commander 2000 feet up in the air observing and giving firing commands direct, is the latest situation in aerial adjustment brought about by the use of the radio telephone.

Obviously, it cuts the time in field artillery response. Under the old system of airplane observation, it took from an hour to an hour and a half to adjust the fire of one gun, the time being taken in giving commands to the battery. By using the radio telephone and giving the firing commands direct,—as can be done by the aviator if he is a trained artilleryman,—the time for making all shifts and range changes can be more than quartered; and in this same less-than-one-fourth of the time, more than one gun can be brought into the action, and even the fire of a whole platoon.

These are actual results from recent experiments with the radio telephone between an airplane from Rockwell Field, San Diego, Cal., and a battery of field artillery training at Camp Kearney.

The aeroplanes used in these experiments have been the Curtiss JN4-H equipped with SCR 68 sets. An SCR 59 set has been used on the ground with SCR 53 antenna unit. (Radio phone.) The practice work is being carried on at regular intervals.

Brigadier General Hand, commanding the 16th Field Artillery Brigade, in giving his report of two days of cooperation between airplane and battery in the earlier days of this practice, has shown incidentally of what stuff aviators are made. Following is an extract from the General's report:

"Yesterday and today we have had firing by aerial adjustment from airplane using the telephone. The ground aerials were set up right at the battery, the executive officer wearing the telephone headdress. All the conduct of fire was by an aviator.

"The aviator who did the adjustment received the first lesson in adjusting fire by me 15 minutes before he went up, and that is all he knew about artillery fire. He was very bright, however, and on his first problem gave the proper commands for shifting his gun into its target and all the proper range changes throughout precision adjustment, including improvement fire. The first problem was 22 rounds, and lasted 19 minutes from the time he left the ground until the last shot. I had him actually give the firing commands, and he sent us no sensings whatsoever. In other words, he was battery commander. The second problem he secured his adjusted range and fired six rounds in improvement fire, making a total of 16, in 14 minutes. Included in this 14 minutes, he had given the commands to bring in the second gun. This morning, he went up, adjusted two guns of a platoon separately, brought in the whole platoon in fire for effect, making his corrections properly, and total time from his leaving the ground to last shot—21 minutes; total rounds fired—47.

"We all were greatly pleased with the results, and to my mind it means a revolution in aerial adjustment. If the aviator is a trained artilleryman, he can handle this fire with the ease, speed, and facility which one could do under the very easiest of terrestrial observation conditions. There was none of the long, tiresome delay such as I have been used to under our old system, as, you know, it took us about an hour or hour and a half, if we were lucky, to adjust one gun by airplane. The ship flew at about 2000 feet. I don't see why it wouldn't be possible to even pick up a fleeting target and adjust shrapnel fire with all the guns. Of course the height of burst might give him trouble, but take it on the proper proportion of air and graze, the trained field artillerymen should be able to handle it, and possibly one could get a very good idea after practice by rating the relation of the pattern to the burst, and be able to tell something about the height.

"However, to sum up my whole observation so far, I believe from now on where the phone can be used, and we have trained observers, they should give the firing commands direct instead of sending sensing down, and waiting for the ground people to transpose them to the battery. The ship we used had only one-way communication, but in a few days they expect to have apparatus so that we can also talk from the ground. That will make everything simple.

"I forgot to tell you that we purposely gave him a good error in deflection each time he was up, and we had no difficulty in making the proper shift. The accuracy of firing speaks for itself. In one problem he had three target hits during improvement and another one two. . . ."

FOREIGN NEWS

Ready to Fly to America

London, Feb. 16.—The 670-foot airship is ready at Glasgow awaiting favorable weather for a trans-Atlantic flight to America, the *Daily Chronicle* states.

The trip is expected to take eight days without stop (round trip). The airship will carry thirty tons. Strikes prevented an earlier demonstration, it is averred.

The machine is driven by six powerful engines under dual control. It is expected to be capable of forty hours' flight at a speed a little under 100 miles per hour.

Army Arranges Aeroplane Courier Service In Europe

Berlin, Feb. 18 (by the Associated Press).—American officers are endeavoring to arrange for an aeroplane courier service to connect various military missions at different points in the Central Empires and in new states with the American base in France. Present communications are difficult and unsatisfactory, particularly with Prague and Warsaw.

Germans Have Built Super-Plane

Berlin, Sunday (by the Associated Press).—If the war had lasted a few months longer Germany was prepared to surprise the world with an enormous aeroplane. The new giant of the air, which was planned by Harold Wolff, an engineer, will have its first trial at Doberitz within a few days.

The new machine is nearly 165 feet from wing tip to wing tip and stands more than 23 feet high. It has six motors with a total of 1,800 H.P., and is driven by four propellers, two of which are forward and two aft. Each of the propellers has four blades. The two motors, it is said, can stop simultaneously without affecting any of the propellers or having any result except to reduce the speed of the aeroplane.

Apart from its dimensions and power the new aeroplane is not only equipped with devices enabling the pilots to know at all times their altitude and angle of elevation, but also with devices to tell the absolute as well as relative direction, which it is believed will make flying possible on the darkest night and in the thickest fog. This device is an improved radio direction finder.

French Aviation Mission Coming to the United States

Paris, Feb. 16.—On March 8 a French aviation mission will leave for the United States with the object of demonstrating the degree of efficiency French aeroplanes have attained. The mission will take with it five of the fastest machines that have been turned out, of various makes.

The itinerary of the mission covers New York, San Francisco, Los Angeles and New Orleans, with a return to New York, the various stage sbeing covered by air. The mission will take with it a collection of paintings and photographs illustrating air episodes of the war. These pictures will be put on exhibition.

Huge Handley Page Machine Makes Long Flight

A Handley-Page aeroplane, fitted with four 350 H.P. Rolls-Royce engines, flew from Belfast to Sheffield on January 18. The total weight on board was 12 tons, including a crew of seven and a half a ton of baggage. The time taken by the flight was 2 hours and 35 minutes.

Flies Across Mediterranean

Lieut. Roget and Captain Cole, in a military biplane, propelled by a 300 H.P. motor, succeeded in flying across the Mediterranean from Marseilles to Algiers on January 26. They started from Istres in Bouches-du-Rhone at 2 A. M. and landed at Algiers five hours later. After a rest of about an hour they set off on the 500-mile journey back to France, but were forced to land at 7 P. M. at Rosas in Catalonia, having lost their way in the mistral and flown for about 1,000 miles over the Mediterranean, which they crossed twice.

Germans Have Surrendered 1,700 Aeroplanes to British

London.—In behalf of the Government it was announced in the House of Commons that the Germans had turned over 1,700 aeroplanes to the British Army.

No Zeppelins In Jutland Battle

A Zeppelin officer, discussing the Jutland battle with a member of the Allied Naval Commission in German waters, said it was not true that they had any Zeppelins on reconnaissance on the day of the battle. Had that been the case, the German fleet would certainly have avoided battle, the German officer said.

Italians Developed New Observation Balloon

Rome.—The chief of the Aerostatic Section of the Italian Army, Major Avoria and Signor Prassove, Director of the Italian Army Aircraft Works, produced, just prior to the signing of the armistice, a new type of observation balloon, which proved much more satisfactory than the Parseval-Sigsfeld or Tribolal Caquot balloon. The new type is essentially a spherical aerostatic fitted with what are equivalent to stabilizing fins and acting as a kite. It may be employed in winds of over 55 miles an hour, while the Parseval type could not be used safely in winds exceeding 12 miles an hour. The new type requires less gas and owing to its smaller dimensions, is easily transported and housed, and safer from hostile fire. A further advantage in the employment of mooring cables of smaller section follows from its smaller head resistance, while should the mooring cable snap, the balloon may be navigated as a free balloon.

Dismantled German Ships As Aerial Landing Places

London.—Commenting on the suggestion that Germany's battleships be destroyed rather than distributed among Allied powers, a British publication suggests their utilization as aerial landing stations in trans-Atlantic air lanes. Mid-Atlantic stopping places of this kind would certainly be an excellent field of utility for obsolete warcraft.

Airwomen Banned By England

London.—An order has been issued oy the Air Council forbidding women in the Woman's Royal Air Force from learning to fly, owing to the shortage of aircraft supplies. The restriction is said to be of temporary character only.

British Aeronautic Industry Has Tremendous Capacity

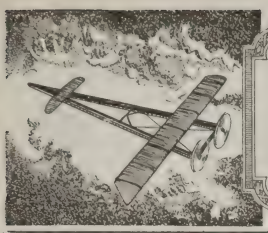
London.—The Advisory Committee of the Ministry of Reconstruction appointed to consider the establishment of new industries has estimated that existing aircraft factories in England are capable of producing 40,000 aeroplanes and 30,000 motors a year, in addition to sufficient spare parts to supply replacements for an air force of that size.

Australia Has Commercial Aeronautic Plans

Auckland, New Zealand.—The Minister of Posts and Telegraphs in New Zealand is supporting a movement for the establishment of aerial transport and aerial mail lines between various parts of New Zealand, extending from Auckland to Dunedin, a distance of 700 miles, and between New Zealand and Australia

Mr. L. A. Walsh, the managing director of Walsh Brothers and Dexter, Ltd., aeronautical constructors and engineers, who was in charge of the training of military aviators during the war; has been one of the moving spirits in the development of these plans. Under his direction several types of single and twin-motored flying boats have been constructed, employing Hall-Scott motors for propulsion.

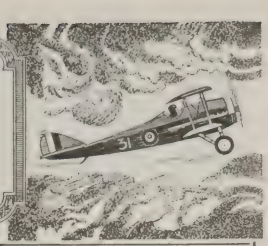
A large number of military fliers will be available for operating commercial aircraft.



British Develop New Airship

London, Feb. 14.—The *Daily Mail* publishes the first particulars of one of the latest types of British rigid airships, the building of which has been done secretly. These vessels, known as the "33" class, are virtually equal in size to the most successful type of Zeppelin, and the preliminary tests have shown that they will equal, if not exceed, Zeppelin performances.

Their length is said to be 670 feet and the diameter seventy-nine feet. Weight in flying trim will be more than 600 tons, including a carrying capacity of between twenty-seven and thirty tons. For war purposes she was to have carried four 580-pound and eight 250-pound bombs, also machine and other guns fore, aft and on top.



The Farman "Aerobus" being used in the Paris-London service. Two Salsmon engines are used. Note the wing end ailerons

Model Aeroplane Building as a Step to Aeronautical Engineering

OWING to the enormous inquiries in reference to the light type aeroplane received while the articles on the Ford Motored Aeroplane were being described the author has decided to give specifications and general details for building a motorcycle engine driven machine.

Some people have an idea that a motorcycle engine is not powerful enough to propel a machine through the air, but this idea is incorrect, because years ago A. V. Roe, of England, proved that he could fly with but 3 horsepower, this was not a mere hop in the air and then back to earth again, but a real honest straightway flight.

Again our Mr. Sellars flew a quadruplane having only an 8 horsepower motorcycle engine for his power plant and he is officially credited with successful flights of a mile or more. These were only experimental flights and no doubt longer ones could be accomplished if the designer so desired.

These machines were not as efficient as the machines of to-day because the aeroplane builders of those days did not have the dope to go by and very little was known about lift coefficients, etc., and it is marvelous to think that these pioneers accomplished as much as they did with the meager figures and data they had on hand.

Emil Laird, a bright young man of the Illinois Model Aero Club, startled the aviation world a few years ago by building a little biplane of about 20 feet spread and powered with a special cylinder air-cooled motor of light weight which was made of cylinders of a well-known automobile motor. This motor of Laird's was rated at about 12 h.p., but it was powerful enough to carry him all around the United States giving exhibitions at the fairs.

Later Laird built a machine powered with an Excelsior motorcycle engine and it was a good flyer. The only fault that the designer could find with it was that the engine heated up badly and the flights were shortened thereby. The heating up of the engine may have been caused by one of a few reasons, namely: overload caused by the propeller being too high pitch or too large diameter, engine not timed properly for the speed of engine or engine running wild due to propeller being too light pitch or diameter. A motor bears up unless we have the particular motor near us and we make a careful investigation of the case.

Recently a photograph of a motorcycle engine driven monoplane was shown in AERIAL AGE and the designer claimed a speed of over 50 m.p.h. with a stock motorcycle engine.

We can get encouragement by looking back to the days when the Wrights flew a machine with a great spread of wing and drove it through the air with twin propellers turning in opposite directions by a bicycle chain transmission driven by a 12 h.p. motor, and you will be amazed when you hear that the lifting efficiency of the wings was only 70%.

Later Nieuport developed a monoplane which has since became famous for its great speed for low horse power and which flew at the rate of 68 miles per hour with an 18 h.p. two cylinder opposed motor.

The foregoing well-known machines are mentioned merely to give the reader encouragement and to give him something as a guide, and by which he can check performances.

Drawings will be given showing the power plant which is a three cylinder "V" motor made up from three stock motorcycle cylinders and which should develop about 25 h.p., also drawings showing general construction and assembly of the machine will be given.

Fittings will not be described, as the fittings that were designed for the Ford Motored Aeroplane can be used for this machine. (In answer to numerous inquiries and for those who wish to know where they can purchase metal fittings and machine work, I refer you to The Jennings Machine Works, Uniontown, Pennsylvania, who have made a specialty of making fittings for the machine described in the preecding articles for a nominal sum.) The general construction will be much the same only over all dimensions and wing curve will be different.

Model Aeroplane Contest

We have received many entries for the contests from all over the country, and most of the entrants ask for an answer to their letters or post cards as the case may be.

It is impossible to answer all of these communications, and in the future we will enter the applicant's name and he will be eligible to complete. In fact any builder or flyer of model aeroplane is eligible, and it makes no difference what type or make of machine the model is patterned after so long as the entrant has built it himself.

This information is for some readers who think that the models must be built according to drawings which appeared in the "Elementary Aeronautics" columns.

Model Curtiss J N 4

The Model Curtiss JN4 shown in the accompanying illustration was built by Harold Morehouse of Detroit, a member of the Illinois Model Aero Club and now employed by the Dayton Wright Company as draughtsman. The model is correct in every detail, the controls working and connected dual as on the big machines. The covering is tracing cloth such as found in draughting rooms, the sizing being washed out of it. It is fastened in the regular way and doped. It is interesting to compare these photos with those of a large machine and note the resemblance to its large prototype.

Model of a Curtiss Aeroplane which shows careful construction. Controls can be operated as in the big machines

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Intelligent Female (to balloon officer of observation sausage): "I wonder you don't have a ladder or a fire escape or something of that sort instead of just having that rope to climb up and down."

Aerodrome Proverbs

It's the last bump that breaks the chassis strut.
A switch off in time saves nine days in the repair shop.

"Owed" to a Night Bomber

Hear! Meccano, ere you crank,
This foolish looking flying tank!
Let me on your mind impress
With the utmost earnestness,
Grasp this order without fail,
Don't get tangled in my tail.
Knight o' the sparkplug, hear my vow,
There will be one hellva' row,
Take it even now from me,
It'll be the end of you an' me.
If you'd escape my rage
Guardez vous mon empennage.

From *The Olympian.*

Tailspin Mac takes a ride under gosport system
(From "Rich Field Flyer")

I ought to get a good job during the election.
Why?
I've spent the last four years ladling out "dope."

Talking about American flying bobbies. "Yes, your wushup, I was on duty in Section XII when I saw the prisoner. He was driving his plane at a furious pace and flying on the wrong side of a cloud. Held up my hand to stop him, but he took no notice, and after nearly colliding with a nursemaid on her aerial pram, he crashed right into the doorway of the 'Aviators' Rest,' causing the same to rock and nearly break from her guys."

From *Aircraft* (London)

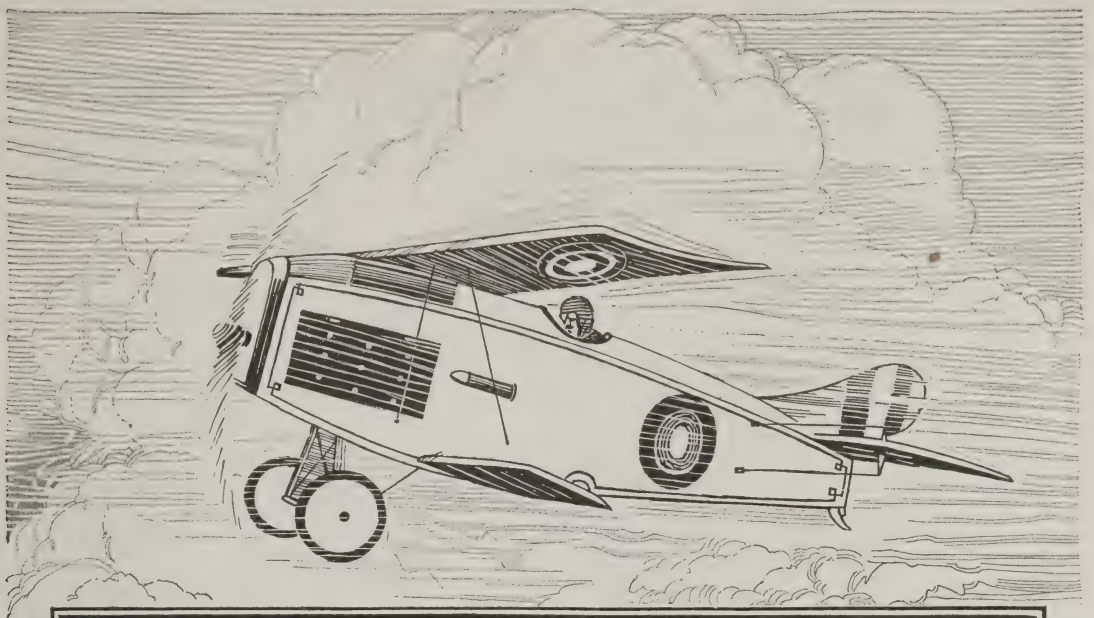
It was a wet day, and the 'bus was skidding all the way up Ludgate Hill.

"What's the matter, conductor," asked the nervous old gent in the corner.

"Driver's just been demobilized from the R. A. F., sir, and when he saw that aeroplane overhead, sir, he got the wind-up and tried to do the Immelman turn."

America has decided to have Flying Policemen. For the love of anything, don't drop the "F" from the adjective, Mr. Printer, or the Force will think we've done it on purpose.—*Aircraft.*

Air-Raided Padua



A heritage of Ilium's glory vast,
O "happy Padua," to thee belongs!
For here Antenor came, his trials past,
Whose ancient fame the Mantuan bard prolongs;
Here Dante dwelt and here he saw the throngs
Of shades within Inferno's gloomy bound;
And here once Petrarch sang his sad, sweet songs
Of "ceaseless sorrow" that loved Laura crowned
And make his tomb at Arqua, still a shrine renowned.

Thy storied name is crowned with memories bright,
And at its bidding come from History's page
Majestic shades of Rome's young, growing might,
By Livy told, and read from age to age.
Thou art the goal of many a pilgrimage—
Of Art and Learning thou art still a shrine
That guards for all the world rich heritage.
Loved still art thou by all the Muses nine—
'Neath blue Italian skies fair rise thy domes divine!

And not alone to thine own clime and race,
"Fair Padua, nursery of arts," hast thou
Been inspiration; thou hast won a place
On page of him to whom all poets bow
As King; Bianca and fair Portia now
Lend thee a grace that every reader thrills
And with their beauty's spell they thee endow.
But stay; What is that sound that o'er thee shrills?
What shadow dread flits from the Euganean hills?

Now o'er thy cupolas and towers high
There hover birds of prey on ruin bent;
A vandal foe to Padua draws nigh,
His winged couriers to thee are sent
And on thy shrines drop from the firmament
Dread bolts that far and wide destruction spread.
Shall storied Padua be in ruin blent?
A foe has come who spares nor quick nor dead—
'Gainst Art and shrines divine Thor's flaming bolts are sped!

—H. T. Sudduth, in the *New York Times.*

The Christmas "Bullet"— Valsparred, of course!

The Christmas "Bullet," is a business-like looking machine, designed by Dr. William Whitney Christmas. It is the first "strutless" biplane. The wings are flexible and during flight they bow, giving them the appearance of a bird's wings.

Equipped with a Liberty Six, which is rated 185 h.p., a speed of 197 miles per hour was made by this plane at Government Experimental Field No. 1 (near Central Park, L. I.) on December 3rd and 7th, before Col. Harmon and his staff.

Naturally, Valspar was used on the varnished portions of this plane. No other varnish made is elastic enough to stand the terrific vibration of this machine, whiz-z-z-ing through the air at 197 miles an hour.

Valspar resists *all* of the destructive effects of high speed and hard usage in airplane service and retains its protective qualities long after ordinary varnish requires renewal.

In constant use in the air service of the Allies during the war, Valspar was the one varnish that satisfied *all* of the exacting requirements.

Our Airplane Department will gladly afford information and assistance in solving your varnish problems. To Purchasing Agents and Superintendents of Production: We will send our book on airplane finishing free on request.

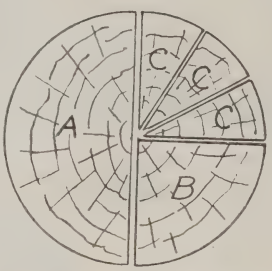
Dipping, Spraying and Brushing coatings of all kinds, Quick-Drying Insignia Colors.

(Continued from page 1241)



three methods which have been outlined it is generally green and wet with steam, and must be thoroughly dried before being either stored or made into plywood. The drying process is a very simple one. It consists merely in drawing air, which has been dried and heated by passage over steam pipes, through the room or rooms in which the veneer is stacked. A temperature of 100 to 110 degrees Fahrenheit is maintained. When the air has become nearly saturated with moisture from the veneer it is sucked out by fans that keep up a continuous circulation. A drying period of from 12 to 13 hours is sufficient, as a rule, for veneer which does not exceed 1/16 inch in thickness, and for greater thicknesses a proportionately longer time is necessary.

Stacking Veneer.—It is most important that the sheets of veneer be so stacked as to insure a ready access of air. The methods employed depend largely on the size and shape of the stock. The comparatively long and narrow sheets from the veneer saws or the slicer are placed in "tooth racks" which consist of pickets about 30 inches long placed in pairs, their lower ends fitted into mortises cut in a piece of scantling so that the clear space between them is ¼ inch. The veneer is supported every 2 or 3 feet by these pickets. Unless the sheets are fairly thick two are placed back to back in these racks and if they are not more than 12 to 15 inches wide they may be stacked edge on edge, two or more deep. The air has always full access.

What is known as the "protected end" method is employed when the sheets are wide and short; that is, not more than 3 feet long. Light boards with vertical grooves cut in them every 3 or 4 inches replace the pickets. The distance between these parallel boards or holders is varied according to the length of the veneer sheets, which are slipped into the grooves. In this way the ends of the sheets are protected, or prevented from cracking and warping while drying.

For rotary cut veneer—which for the most part is short and very wide—a third method called the "hanging process" is used. Lengths of from 6 inches to 3 or 4 feet, or even more, and widths of any dimension can be handled. Pairs of parallel wires, spaced 15 inches apart, are strung across the room about 5 feet above the floor. Each pair of wires supports a number of light wood cross members that project a little below the wires, and near their lower edge are driven nails which project an inch on each side of the stick. The sheets of veneer are hung from a cross-stick by these nails, which are struck through the piece close to its upper edge. When the width of the sheet is greater than the distance of the wires from the floor it is folded, and the other edge of the sheet is supported by the nails on the opposite side of the cross-stick. Very wide sheets and lengths greater than 20 inches are ordinarily suspended from two or more sets of wires.

After the veneer has been dried it is taken either directly to the cutting and gluing rooms to be made into plywood or to the storeroom for future use. Here it is kept in low piles containing all the veneer cut from one log, and marked with the log number. Since it may have absorbed some moisture while in the storeroom, veneer, before it can be used, must first be put through a re-drying press. Such a press consists of a series of heavy, hollow iron plates, sliding up and down in an open steel frame, heated by live steam and forced together both by their own weight and by the pressure of steam acting on a piston. Only 5 or 10 minutes is necessary to complete the re-drying of veneer of the usual thickness. Lack of care in this operation may cause a glossing of the surface of the veneer that is apt to render gluing difficult.

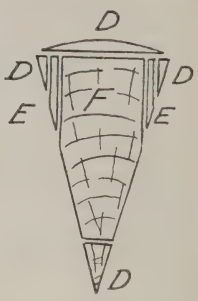


Fig. 5

Fig. 6—Front view of slicer

Fig. 7—Veneer saw and flitches

The Manufacture of Plywood

The first step in the manufacture of plywood is to cut the sheets of veneer to gross lengths and widths which are such that an ample allowance is made for later trimming to the exact dimensions specified in the order to be filled. Uniformity and speed are secured by the use of double header saws, both cross-cut and rip. With sawn or sliced veneer the sheets are usually so narrow that two or more must be spliced together.

Jointing and Splicing.—To secure square, straight edges the sheets are put through a jointer. A sufficient number to make a thickness of 3 inches are placed on the bed of this machine and are carried over a knife, gripped between a series of rolls and a roughened, endless chain. But one man is needed for the operation of a jointer. The veneer now passes to the splicer, where enough sheets are joined to give the required width. The operator takes up two pieces of veneer, places them on the smooth bed of the splicer and, pressing the edges together, starts the sheets under a roller which forces them still closer. At the same time a strip of gummed paper an inch wide is moistened and drawn through the roll with the veneer. This serves to fasten the pieces together. It is applied only to the outside surface of the outer plies of veneer, because if it were used on the inner surfaces of the plies the panel would not be waterproof. No glue whatever is applied to the joint, which is perfectly flexible. In a panel the inner layers of veneer, for which, as a rule, the softer, cheaper woods are used, do not need splicing, as they are rotary cut and hence can be of any width. Two men are necessary to run a splicer.

Gluing Up Panels.—The operation next in

(Continued on page 1285)

CONFIDENCE

To enjoy flying it is essential to have absolute confidence in the "ship" you are in, either as pilot or passenger.

Why you must have confidence in the

1. We have been constantly building aircraft for thirteen years—since 1906.
2. Our workmen are skilled to the highest degree because as much care is taken in employing them as selecting sound material.
3. The construction of our "ships" is daily inspected by the men who have put thirteen years of continuous study and building into development of airplanes and seaplanes.

We specialize in designing and constructing individual pleasure and commercial aircraft.

YOU MUST HAVE THE BEST—reliable —modern—AIRPLANE OR SEAPLANE.

Where Divisions Are Located Overseas

Washington, January 23rd.—The War Department made public a list giving the latest location of all divisions in France, as follows:

1—Montabaur, Major Gen. E. F. McGlachlin.
2—Heddesdorf, Major Gen. John A. Lejeune.
3—Andernach, Major Gen. Robert L. Howze.
4—Bertrich, Major Gen. Mark L. Hersey.
5—Esch sur Aizette, Major Gen. Hanson E. Ely.
6—Aigny-le-Duc, Major Gen. Walter H. Gordon.
7—Euvezin, Major Gen. Edmund Whittemeyer.
26—Montigny-le-Roi, Major Gen. Harry C. Hale.
27—(On priority,) Montfort, Major Gen. John F. O'Ryan.
28—Hudicourt, Major Gen. William H. Hay.
29—Bourbonne les Baines, Major Gen. Charles G. Morton.
30—(On priority,) Balloon, Major Gen. Edward H. Lewis.
31—Skeletonized, part on priority, part sailed.
32—Rengsdorf, Major Gen. Wm. Lassiter.
33—Diekirch, Major Gen. George Bell, Jr.
34—Skeletonized, part on priority, part sailed.
35—Commercy, Major Gen. Thomas B. Dugan.
36—Cheny, Major Gen. W. R. Smith.
37—(On priority,) Wormhoudt, (to Le Mans,) Major Gen. Charles B. Fansworth.
38—Skeletonized, part on priority.
42—Ahrweiler, Major Gen. Clement A. F. Flagler.
77—Chateau Villian, Major Gen. Robert Alexander.
78—Semur, Major Gen. James H. McRae.
79—Souilly, Major Gen. Joseph E. Kuhn.
80—Ancy-le-Franc, Major Gen. Samuel D. Sturgis.
81—Mussy sur Seine, Major Gen. Charles J. Bailey.
82—Prauthoy, Major Gen. George B. Duncan.
84—(To be skeletonized at Le Mans, Nov. 28.)
86—(Skeletonized—part for replacement, part to return to United States.)
87—St. Nazaire, Brig. Gen. William F. Martin.
88—Laigny, Major Gen. William Weigel.
89—Kylburg, Brig. Gen. Frank L. Winn
90—Berncastel, Brig. Gen. Joseph P. O'Neill.
91—(Designated for Lafaret—Bernard—to early return, Le Mans,) Major Gen. M. H. Johnston.
92—Le Mans, Brig. Gen. James B. Erwin.

Depot Divisions

41—St. Aignan, Brig. Gen. Eli Cole, U. S. M. C.
83—Le Mans, Major Gen. E. T. Glenn.
85—Toul, Major Gen. Chase W. Kennedy.
39—(Skeletonized for replacement and return to the United States.)
40—Revigny, Major Gen. F. S. Strong.
8—Pons.

Advanced Ratings for Overseas Officers for Distinguished Service

Advanced flying ratings have been recommended to 20 officers of the Air Service who have distinguished themselves in action overseas. Among the officers so recognized are Lieut. Col. Wm. Thaw, Major David McK. Peterson, Capt. Edward V. Rickenbacker, Capt. Reed G. Landis, Capt. Douglas Campbell, Capt. Edward G. Tobin, and Lieut. L. O. Donaldson, all credited with having shot down five or more planes.

These ratings are the first awards issued by a Board formed under the direction of Major General Wm. L. Kenly, Director of Military Aeronautics, to pass upon the qualifications and merits of flying officers who have distinguished themselves in action, with a view to awarding them such ratings as their achievements and abilities may warrant. This Board is composed of Col. Townsend F. Dodd, Lieut. Col. B. F. Castle, Major Horace M. Hickam, and First Lieut. Sidney T. Thomas, of the Army Air Service.

The ratings awarded are those of the Junior Military Aviator, carrying an increase of 50% base pay for flying duty, and the Military Aviator carrying 75% increased pay. Before the war the rating of Junior Military Aviator was given after certain flying tests were passed and that of Military Aviator only after three years' experience as a Junior Military Aviator. During the war the rating of Reserve Military Aviator was created, and a law was passed which authorizes the promotion and appointment of officers to advanced ratings for distinguished service in action without examination. The operations in the United States are now vested in the above mentioned board.

There follows a list of 20 officers just recommended by the board for these ratings, six of whom are reported deceased. The ratings are indicated by the letters J.M.A., Junior Military Aviator, and M.A., Military Aviator, the second being the senior rating.

Lieut. Col. Wm. Thaw, M.A., Pittsburg, Pa.; Maj. David McK. Peterson, M.A., Honesdale, Pa.; Capts. Edward V. Rickenbacker, J.M.A., to M.A., Columbus, O.; Reed G. Landis, M.A., Chicago, Ill.; Douglas Campbell, M.A. Mt. Hamilton, Calif.; Edgar G. Tobin; J.M.A., San Antonio, Texas; First Lieuts. Louis G. Bernheimer, J.M.A., New York, N. Y.; Wm. P. Erwin, J.M.A., to M.A., Chicago, Ill.; Robert F. Raymond, J.M.A., Newton Center, Mass.; Donald B. Warner (Bomber), to J.M.A., Swampscott, Mass.; James A. Keating, J.M.A., to M.A., Chicago, Ill.; Second Lieuts. Earl W. Porter (Observer), J.M.A., Chicago. Ill.; John O. Donaldson, M.A., Washington, D. C., and Charles W.

THE LIBERTY STARTER

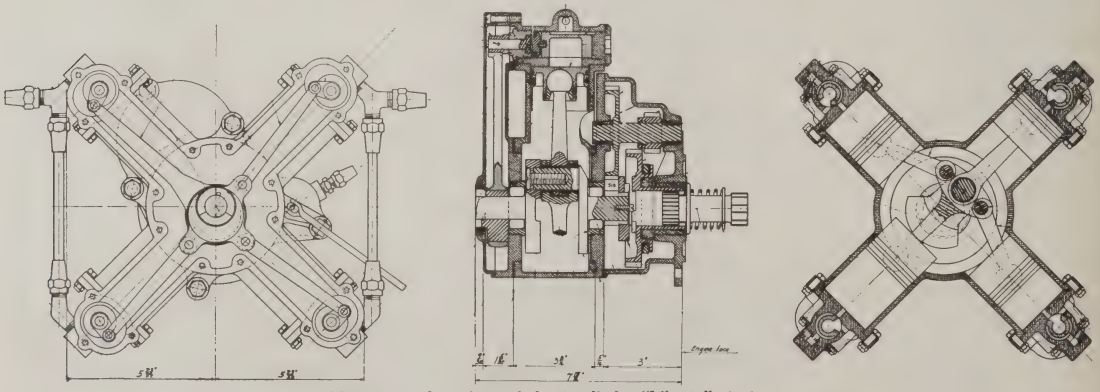
THE Liberty Starter is a four cylinder racial two cycle air motor and compressor with a bore of 2¼" and stroke of 2¼". As a starter it has 9 to 1 gear reduction on final drive to motor. It pumps direct drive at engine speed.

The valve construction is a semi-rotary of the Corliss type, having universal joint action to rocker shaft. The driving member between the rocker shaft and the valve not only performs the function of a universal joint, but is so constructed that the air pressure in valve chamber presses it against the end of rocker shaft bearing sealing the chamber airtight. It also permits the valve to be floated and held against the seat by the air pressure. This entirely eliminates the use of troublesome soft packing where valve actions are used.

The crank shaft is carried on roller bearings. All parts are idle except when brought into action as a pump or a starter.

The Liberty Starter has been approved and is being used by the United States Navy. The Japanese government recently placed an order for a large number.

The usual attachment on such as the Liberty, Hall-Scott, Renault and Bugatti motors is by bolting direct the flange of starter to the flange on motor. A suitable flexible coupling is provided for the drive to the crank shaft. Where flanges are not provided, such as the Curtiss V.X., etc., arms are provided for supporting the starter on engine runners.



Although it weighs but 30 pounds completely the Liberty Starter is capable of starting the largest engines in service, such as the Liberty, Hall-Scott, Renault, Bugatti, etc. Its compactness lends itself to the requirements of installation on aeroplanes where but little space is available for "accessories" of any kind; though the "Liberty" can hardly be termed an accessory for it has really become a necessity.

Its length is only 8". It cranks the engine at 150 R.P.M. or more, and it replenishes its own energy in half a minute. The tank, weighs 12¼ lbs., bringing the total weight of the outfit to 49 lbs.

After the engine is started, the Liberty starter automatically disengages and remains disengaged until it is needed again either as a starter or compressor.

When the air pressure in the tank becomes low, the compressor is put in operation by pressing a button on the control valve while the engine is running at low speed. When engaged, the engine must be run at from 1200 to 1400 R.P.M., and when the pressure has been brought up to 230 lbs., the mechanism automatically becomes disengaged.

Hundreds of these starters are in service throughout the country, and the New Mail Service is installing them in the larger machines.

Cited for Distinguished Service

The commander-in-chief, in the name of the President, has awarded the distinguished service cross to the following named officers and soldiers for the acts of extraordinary heroism described after their names:

First Lieut. William P. Frank, observer (Air Service), 20th Aero Squadron, first day bombardment group. For extraordinary heroism in action near Buzancy, France, October 23, 1918. While flying in the rear of a formation, returning from a bombing raid, Lieut. Frank's machine was attacked by three hostile planes, Fokker type. Lieut. Frank was wounded and rendered unconscious early in the encounter, but upon recovering he shot down a Fokker which was attacking the leader of the formation and drove off two others which were pressing him from the side. Home address, Paul A. Frank, brother, 2349 Michigan Avenue, Chicago, Ill.

First Lieut. Andre P. Gundelach ,deceased (Air Service), pilot, 96th Aero Squadron. For extraordinary heroism in action near Buxieres, France, September 12, 1918. Lieut. Gundelach, with Second Lieut. Pennington H. Way, observer, volunteered for a hazardous mission to bomb concentrations of enemy troops. They successfully bombed their objective, but while returning were attacked by eight enemy planes. Their plane was brought down in flames and both officers killed. Next of kin, Maj. C. D. Meyer, Q. M. C., 5802 Kenmore Avenue, Chicago, Ill.

Second Lieut. Pennington H. Way, deceased (Air Service), observer, 96th Aero Squadron. For extraordinary heroism in action near Buxieres, France, September 12, 1918. Lieut. Way with First Lieut. Gundelach, pilot, volunteered for a hazardous mission to bomb concentrations of enemy troops. They successfully bombed their objective, but while returning were attacked by eight enemy planes. Their plane was brought down in flames and both officers killed. Next of kin, Mrs. Pennington H. Way, wife, St. Davids, Pa.

First Lieut. Richard D. Shelby, Air Service, 139th Aero Squadron. For extraordinary heroism in action near Verdun, France, October 10, 1918. Lieut. Shelby encountered six enemy planes at a very low altitude strafing our trenches. He immediately attacked and dispersed the enemy planes and by skilful maneuvring brought one of the planes down just behind his own lines. Home address, W. A. Shelby, father, Rosedale, Miss.

First Lieut. Karl J. Schoen, deceased (Air Service), 139th Aero Squadron. For extraordinary heroism in action near Aincreville, France, October 1, 1918. While leading a patrol of three machines Lieut. Schoen sighted nine enemy planes, Fokker type, and immediately attacked them. Although greatly outnumbered, he destroyed one of the planes and put the others to flight. He was killed in action October 29 and has been officially credited with destroying seven enemy aircraft. Next of kin, Maruine Estelle Schoen, wife, 5001 College Avenue, Indianapolis, Ind.

order after the splicing is that of gluing up the veneer to form a "panel" or "plywood." The "finish" or outside "plies" of panel that have just come from the splicer are not put through the gluer. Only the inner layers or "cross-bands" pass through this machine, which applies the glue to both surfaces of the wood. As a "cross-band" comes from the gluer it is laid upon a sheet of finish veneer. When the panel is only three ply another layer of finish is next placed upon the "core" or cross-band, with its grain at right angles to the grain of the core, and parallel to that of the first finish ply. If, however, the panel is to be of five-ply construction, a relatively thick core or "center," usually of chestnut, gum or poplar, and often of comparatively poor quality, is laid upon the first cross-band, on top of this comes another cross-band, and lastly the outside finish ply. Veneer used for cross-banding is generally the cheaper, rotary cut gum or poplar. Since it can be obtained in any width, splicing is unnecessary. Panels, of course, may consist of any number of plies. Symmetry requires that the number be odd. Always, the grain of adjacent plies is at right angles.

Pressing the Panels.—The glued panels are now placed in piles upon a "caull," a thick, rigid board of laminated construction. Between each layer of plywood is inserted a thin waxed board. When the piles are 3½ or 4 feet high another caull is put on the top and the whole then placed in a hydraulic press. But instead of resting directly on the bed of the press the lower caull rests upon several shallow I-beams placed crosswise of the bed. The same number of I-beams are similarly put on top of the upper caull. The I-beams project beyond the sides of the pile and heavy turn-buckle clamps are attached to corresponding ends above and below. The purpose of these clamps is not to aid in applying the load, but as the pile compresses or packs down slightly, due air and surplus glue being squeezed out, the slack in the clamps is taken up, and therefore, when the stack is removed from the press, it is still under great pressure caused by tension in the clamps.

The pressure while the stack is in the press depends upon the character of the panels; that is, their size and thickness, and the species of wood of which they are made. For lighter work 100 pounds per square inch is satisfactory, but for the largest, heaviest type, a pressure of 300 pounds per square inch is needed. Excessive compression causes the glue to squeeze out between the joints and results in a "starved" joint. The operation of pressing takes only about five minutes.

After removal from the press, the stack of panels, tightly clamped together, is carried to a drying room. Here it remains as a rule for 24 hours in a temperature of 70 to 90 degrees Fahrenheit. When this time has elapsed the clamps are loosened, the upper caull removed, and the panels piled up in the same room, separated by small sticks so that they are entirely exposed to the dry air kept circulating through the room. Forty-eight hours is allowed for this second drying, after which the panels are ready for cutting to size and sanding.

Cutting and Sanding.—This operation is done with rip and cross-cut saws which trim the panels to the specified dimensions. They are now ready for the final process, that of smoothing the surfaces in a sanding machine. The panels are drawn in by steel rolls and passed over sand-paper of grades ranging from No. 1½ to No. 0. Ordinarily this is sufficient, although sometimes a panel has to be put through the sander a second time. For very fine work a "finish sanding" on a belt re-sander with No. 00 paper is required. Whenever plywood is designed to carry important stresses care must be taken, especially if the face plies are thin, not to remove too much material in the sanding process in order, for instance, to reach a specified total thickness.

Minor defects that occasionally appear in finishing work, caused, perhaps, by slight imperfections in the wood or careless workmanship, are repaired by an expert, who generally cuts out the part containing the flaw and inlays new wood.

(The writer wishes to express his appreciation to the Messrs. Kline of the Louisville Veneer Mills, Louisville, Ky., for their kind assistance in securing the material for this article.)

(*Continued from page* 1261)

15,000 feet and an increase of two and a half percent in the horizontal speed was obtained by removing the nose radiator, streamlining the nose and fitting on side radiators.

Wind tunnel tests on a large model have indicated that for a given amount of heat dissipated, the total head resistance of the fuselage is from ten to fifty percent greater when fitted with a nose radiator than when a free air radiator is used, the larger difference having occurred when the same type of cooling section was used in both cases, and the smallest difference having occurred when a high resistance radiator was in the nose.

There remains still one point in favor of the nose radiator: When it is shuttered the head resistance of the machine decreases, whereas the shuttering of a free air radiator increases the resistance of the machine. But this point may be practically dispensed with at once. An aeroplane, which in constructed in such a way that a nose radiator can be installed on it, is usually of such a design as will permit the use of retractable radiators—side radiators which can be drawn into the fuselage, or a radiator underneath the fuselage which can be drawn up into it.

The Wing Radiator

There is at the present an increasing tendency towards the installation of the radiator in the wing; but it does not seem advisable to adopt this location as being exceptionally good without a rather extensive study of its effects. A great number of influences are brought to bear upon the machine which are difficult of solution and should probably be determined from comparative tests in flight.

In connection with the ordinary radiator installation head resistance weight, durability, cooling properties and the ability of pass water are the main considerations; and these are all easily determined in the wind—tunnel and in flight. But the wind radiator brings in its own head resistance (perhaps more aptly called "drag" in this case) weight, durability, loss of lift, increased wing loading, increased angle of incidence, the consequent increase in resistance of the wings, cooling properties and the ability to pass water—and the problem of determining whether it is a good installation becomes more complicated.

From comparative tests in flight on a honeycomb wing radiator, shown in Fig. 15, it is safe to say that this particular type is very bad when installed in the wing.

In this case the horizontal speed of the seaplane was reduced by four and a half percent at one thousand feet, and the rate of climb was reduced by sixteen percent in the first three thousand feet of climb, as compared with the performance of the same machine when equipped with ordinary radiators.

On the basis of these tests the following discussion is given as being the probabilities concerning the wing radiator, as compared with the usual type.

The weight of the radiator wil probably be fifteen percent greater. Assuming a speed of ninety miles per hour, this increase in size suggests that the cooling power of the radiator will be that of a free air radiator at seventy-two miles per hour, and indicates that the resistance to the air in passing through the radiator is 6.3 pounds per square foot. As the tubes in the radiator in question were placed at thirty degrees to the vertical this resistance may be resolved into a vertical compoment of 5.45 pounds per square foot and a horizontal component of 3.15 pounds per square foot. Then, assuming a normal wing loading of 8 pounds per square foot there will be a loss of lift of [(8—5.45) lb. /sq. ft. =] 2.55 pounds per square foot of the surface occupied by the radiator. Now taking the weight of the radiator itself at its normal value of 19.2 pounds per square foot and adding on the loss of lift, we have the effective weight as

$$(19.2 + 2.55) \text{ lb. /sq. ft.} = 21.75 \text{ lb. /sq. ft.}$$

and assuming a lift-drift ratio of six, the power to carry the radiator is

$$(3.15 \times 6 + 21.75) \times .04 \text{ h.p. /sq. ft.} = 1.63 \text{ h.p. /sq. ft.}$$

and taking the heat dissipation per 100°F. mean difference at its normal value of 72 miles per hour we have

$$\text{Figure of merit} = \frac{40.6}{1.63} = 24.9$$

which is extremely high, as the figure of merit of a free air radiator at ninety miles per hour is in the neighborhood of thirteen.

Up to this point the efficiency of the radiator itself as calculated is high; and the higher efficiency has been obtained by procuring a low air speed, as in the case of the nose radiator, and by converting part of the resistance into a vertical component. But it seems probable that a very heavy drag which cannot be calculated is brought into play in changing the direction of the air flow before it enters the radiator and after it leaves it. If the very poor performance of the machine in question is actually due to such a drag, it might be said off-hand that the use of a plate radiator in which the plates ran parallel to the length of the machine would do away with most this injurious effect by allowing the air to flow through the radiator with a very small change in direction.

It is not believed that the air would flow through in such a way, however, because the high pressure underneath the wing acting in connection with the low pressure above the wing should tend to change the direction of the air and force it upward through the radiator. And, furthermore, if the use of a plate radiator would allow the air to flow through with a small charge in direction, a very small amount of air would get through, as the cross-sectional area of the air stream which flowed into the radiator would approximate the projected area (projected along the line of flight) of the wing radiator, and this would be very small. Furthermore, under such conditions the air would flow along the lengths of the plates and would become very ineffective toward the rear becase of its being heated up.

At present any consideration of the wing radiator must of necessity be largely conjectural; and it must remain for further and extensive tests to determine whether it can be made efficient or not. It may be possible to make a longitudinal plate radiator with such a small plate spacing that the loss of lift will be very small; but it is believed that the effect illustrated in Fig. 4 will nulify the cooling properties of the radiator before the desired small spacing is reached. And it is believed that the injurious effect of this type which has been ascribed to a drag entailed in changing the direction of the air which passes through the radiator cannot be disposed of.

"SERVICE"

"NORMA" PRECISION BALL BEARINGS

(PATENTED)

The right perspective on values reveals serviceability as the big out-standing essential today. And any analysis of airplane serviceability shows a most complex division of responsibility among a hundred smaller units that, in themselves, are seemingly insignificant. Weakness in any one of them weakens the structure upon which dependability rests.

"NORMA" Ball Bearings—small, and hidden away in ignition apparatus and radio-electric apparatus—are the standards with the builders of high-grade electrical apparatus because their superlative speed qualities and high factor of safety in speed service are known to give maximum security against bearing trouble—which means maximum security against ignition trouble.

Be SURE. See that your Electrical Apparatus is "NORMA" Equipped.

THE AERO SHOW TO BE FOLLOWED BY AEROPLANE AND DIRIGIBLE RACES AND ONE MONTH AERONAUTICAL CONVENTION

THE Show is a huge success and the organizers deserve great credit. The setting, the exhibits and the attendance —everything is up to expectations.

Thousands of people have attended the Show each day and packed the aisles so that people who came with the intention of ordering planes had to postpone doing so.

The numerous exhibits are described elsewhere in this number.

This Show and the aeroplane and dirigible races and the one month Aeronautic Convention and other events to be held at Atlantic City beginning with May 1st will interest hundreds of thousands of people in aeronautics. The Atlantic City plan will permit actual demonstrations of aircraft to prospective buyers. This plan will greatly facilitate the work of selling aircraft to prospective buyers, who after seeing the aircraft exhibited on the Steel Pier and seeing them in flight during the races, can proceed to the beach or the aerodrome and get a ride on the craft he or she has selected and will be able to place the order there and then for the craft selected.

A great many of the people who are attending the New York Aero Shows will be at Atlantic City to see the demonstrations and races. Many who have just become interested and who probably would not go any further in aeronautics this year, will go to Atlantic City and order planes for use in the summer. Representatives of college groups will look over balloons for the balloon races to be held at St. Louis in the Fall.

Selecting Aircraft for Atlantic City Races

The announcement of the Atlantic City events created additional interest in the New York Show. Prospective entrants for the competitions are looking over the aircraft exhibited at the Show with a view of selecting "winners" for the Atlantic City races.

Tens of Thousands of People to Attend Convention to Discuss New Phases of Aeronautics in Which They Are Interested

The convention aims for the first time in the history of aeronautics to permit thorough discussion of each of the important phases of aeronautics so that people interested in each phase may acquire all the information available on the subject.

The program is most thorough and complete. Tens of thousands of people of different lines of human endeavor related to aeronautics are invited to attend. For instance, on the fifth day, when the "Large Dirigible and Its Value for Transportation" is discussed, there are invited the representatives of railroads, express, steamship and other transportation organizations invited to attend.

For the illustrated addresses on "Aerial Forest Patrol," the Forestry Department of every State are invited. For the discussion of the "Work of Aerial Police Squadrons, and Why Every City Should Have One," the police commissioners of all cities are invited.

For the illustrated address on, and consideration of "Aerial Mail Plans," the Chairman of Post Office and Post Roads Committees of House of Representatives and Senate, and Postmaster General Burleson and 26,000 United States postmasters, and Chambers of Commerce of 13,000 cities are invited to attend.

Likewise for the illustrated addresses on the "Need of Municipal Aerodromes, and the Part To Be Played By Aircraft In City Planning," the Chambers of Commerce and City Planning Commissions of 13,000 cities are invited to attend.

For the presentation of the flags by each State of the United States to the Aero Squadrons representing the States, all the States and cities are invited to send delegates and Army, Navy and Marine Corps to send representatives.

For the demonstrations and illustrated addresses on the "Value of Aircraft for Advertising by Day and by Night," all national advertisers and advertising agents are invited to attend. For the discussion of "Pan-American Aerial Transport," the commissions of the 20 Latin-American Republics are invited to attend.

For the discussion of "Aerial Navigation Instruments for Flying Over Land and Water," aviators, navigators, scientific instrument makers and aeronautic experts are invited to attend.

For the addresses on "Aerial Photography," all the photographers, professional and amateur, and makers of photographic apparatus are invited to attend.

For the addresses on "Aerial Exploration and the Use of Aircraft for Coast and Geodetic Survey," all people interested in exploration and surveying are invited to attend.

For the addresses on "Need of Broader Attitude Regarding Insurance for Aircraft and Aviators," all the insurance companies and agents are invited to attend.

For the addresses on "Aerial Jurisprudence—Aerial Laws and Regulation of Air Traffic," all lawyers, traffic commissioners and police authorities of different countries are invited to attend.

For the Aeronautic Art Day, when an address on "Aerial Painting and Sculpture of Different Countries" will be delivered and exhibition of aerial paintings by Lieut. Farre, Lieut. Ruttan and others, all the prominent artists, managers of art galleries and art patrons are invited to attend.

The engineers are invited to attend aeronautic week, when basic problems of aeronautic engineering are to be considered.

For the discussions of "Meterology—How the Weather Forecasts Can Be Extended and Made More Efficient by the Use of Aircraft in Exploring the Upper Air," also "How the Weather Forecasts Help Aerial Navigation" and "Telegraphic and Climatic Factors in Relation to Aeronautics," people interested in the subject are invited to attend.

For the discussion of "International Medical Standards for Aviators in War and Peace," when reports from different countries will be presented by the highest authorities on the subject, 50,000 medical men are invited to attend.

Every Day Plenty of Aeronautic Activities—Every Saturday Contests

Every day will have plenty of aeronautic activities, as follows:

(1) *Exhibits of aeroplanes, motors and accessories on the Steel Pier.*

(2) *Demonstrations and tests of seaplanes, land aeroplanes, motors, dirigibles, kite balloons, to prospective purchasers.*

(3) *Aerial passenger carrying by seaplanes and dirigibles, and kite balloon ascensions.*

(4) *Moving pictures and addresses by leading authorities on most important phases of aeronautics.*

The contests to be held every Saturday are most interesting. They are:

(1) Seaplane contests (general).
(2) Curtiss Marine Flying Trophy and prizes.
(3) Intercollegiate seaplane contests.
(4) Land aeroplane contests.
(5) Dirigible contests.
(6) Kite balloon speed in ascending and descending, and maneuvering contests.
(7) Parachute competition.
(8) Aviette (bicycles and motorcycles with wings) contests.

The Atlantic City convention is to be a potential factor in starting American aeronautic activities on a permanent basis.

AIRMEN MEMORIAL FUND CREATED BY AERO CLUB OF AMERICA

THE Aero Club of America has adopted the plan to put up a memorial "To the Airmen Who Cannot Come Back" in the famous graveyard at Toul, where Major Lufbery, Hobey Baker, Blair Thaw and other famous Americans are buried, which was proposed to the Aero Club of America at the club's annual banquet by Captain Eddie Rickenbacker, the American Ace of Aces.

Captain Rickenbacker has been selected as chairman of the Memorial Committee and the fund has been started with the following contributions:

Aero Club of America	$500.00
Aerial League of America	500.00
Alan R. Hawley	100.00
Henry A. Wise Wood	100.00
Henry Woodhouse	100.00
Charles Jerome Edwards	100.00
J. Parke Channing	50.00
C. R. Corning	50.00
John Hays Hammond, Jr.	50.00
Augustus Post	50.00
G. Douglas Wardrop	50.00
Evan J. David	50.00
Capt. Herbert S. Mapes	50.00
K. M. Turner	50.00
Lieut. M. Gilbert Whitman	25.00
Lieut. Granville A. Pollock	25.00

It is requested that subscriptions to this fund be addressed to Captain Eddie Rickenbacker, Chairman, Airmen's Memorial Fund, Aero Club of America, 297 Madison Avenue, New York City. Checks should be made payable to the Airmen's Memorial Fund.

Captain Rickenbacker's appeal for a memorial to his dead comrades was most touching. He said:

"I recall a little graveyard just outside of Toul, which is probably the most famous graveyard as far as Americans are concerned. Such men as Lufbery, Hobey Baker, Lieut. Blair Thaw and probably one dozen others are quietly resting there. And for that reason I think in some way we should look into the future and plan for a memorial to these men, as they were the real heroes after all, the men who were the inspiration to us boys who were more fortunate, and who had the good fortune to come back and receive the admiration and the ovation of the multitudes of people of the dear old United States of America.

"I remember I had not arrived in Columbus but a few moments, when going up the main street of the town I saw a temporary memorial 'To the Boys of Columbus,' with their names inscribed on it. Something which will be made permanent to live for centuries thereafter will be erected there. And I thought this evening would be a good time to bring up and suggest such a memorial for this little graveyard just outside of Toul, which we all know so well; and something to perpetuate the memory of the boys left behind. I hope one and all of you will try to think now and then of these boys, and not overlook the fact that we here are not entitled to all of this applause—there are others!

"If I had my way about it, the parents of the boys left in France the mothers, would have the decorations which I have today. In years to come we can say with a clear conscience that those who gave their all for the cause which brought us fame are the men whose memories shall stand out, and the future generations of America's air fleet, America's eagles, will look back with that realization in mind.

"I do not want you to feel that I am trying to bring back something that you want to forget. I do not believe any one of you is trying to forget all of the horrors of this war, yet it is a part of the make-up of the American public to want to forget too soon. Consequently, I suggest again that the Aero Club of America and each and every one of you present will do your share and bit in contributing to this memorial to 'The Men Who Shall Not Come Back.'"

The matter of putting up a suitable memorial to dead airmen in the United States has been given consideration by the Club since the beginning of the war. It was realized at the time that instead of having a monument for each aviator it would be better to wait and have one memorial for all the aviators who lost their life in the fight for humanity and civilization. Therefore a resolution was adopted to that effect and a committee with Admiral Peary as chairman was appointed to outline the plans for such a memorial.

Two suggestions made by the committee, which have been approved and are being carried out are:

(1) To ask every State and every city to present and dedicate a flag to each aero squadron and balloon company whose members were in preponderance from that State or city. The flag is to bear the insignia of the State or of the city as well as the insignia of the squadron itself. This plan has received the enthusiastic approval of the aviators to whom it has been submitted for an expression of opinion.

(2) To place the names of all the airmen who lost their lives during the war on a permanent Honor Roll, to occupy a prominent place in the club house of the Aero Club of America. This plan has also been approved and is being carried into effect.

Transatlantic Flight

Every effort is being made by the Navy Department to get the giant seaplane at the Rockaway training station ready for the proposed transatlantic flight. There is keen rivalry among the navy, the army and the British dirigible for the honor of being the first to cross the ocean. All three machines are theoretically abundantly able to make the flight and, as each is of a different type, the test will offer a chance to compare their different merits.

The naval craft has already carried many passengers, has attained a speed of eighty-five miles an hour and can climb 2,000 feet in ten minutes, thereby proving its abilities. It is intended to have two pilots, who will be seated side by side, and a crew of five men in an enclosed cabin. It has been estimated that the trip between Newfoundland and Ireland can be made in fifteen hours.

The army aeroplane, which is yet to be built, will be of the Glenn-Martin type and will have no pontoons—which would be unfortunate in case it fell into the water. To compensate, its speed will be considerably greater, but it will have to take a longer route—by way of the Azores, landing either in France or England.

Very little has leaked out about the plans for the voyage of the British dirigible, but an expert has already arrived in Newfoundland to pick out a suitable landing place. The British machine is under the disadvantage of possible head winds, as the revolution of the globe throws the lighter aerial envelope from west to east faster than the solid earth.

One great question is that of directing the course of the machines. On such a rapidly moving surface compasses would be unreliable and the sun's position would not offer a sure index of locality. The suggestion is made in the European edition of the *Herald* that the flights take place at night, when the North Star would be a safe guide. It instances the plight of two French aviators who, after crossing the Mediterranean from Marseilles to Algeria, were unable on their return to find the Balearic Islands, where they intended to make a landing, and reached Spain instead.

The Aeronautic Exposition

THE Aeronautic Exposition, being held in Madison Square Gorden and the 69th Regiment Armory, under the auspices of the Manufacturers Aircraft Association, was opened to the public on March 1. The attendance on the opening night created a record, and has been very well sustained during the past week.

The exhibits bear wonderful testimony to the energy and aggressiveness of the American, aeronautic industry, and one calculated to inspire confidence in the possibilities of aerial transportation and sport, as is evidenced in the descriptions of the exhibits in this issue of AERIAL AGE.

The Committee in charge of the Exposition on arrangements. Top row: Fay L. Faurote, Frank H. Russell, S. S. Bradley, Inglis M. Uppercu. Bottom row: G. M. Williams, B. A. Guy, Harry Bowers Mingle, Albert H. Flint

AEROPLANE EXHIBITS

AEROMARINE PLANE AND MOTOR COMPANY

(Garden, South Section, Main Floor)

Aeromarine Model 50 Flying Boat is similar to the Model 40 except that in the latter machine the cabin is closed in by a transparent hood and it is driven by an Aeromarine 130 H.P. Type L engine. The Model 50 is a sport machine designed for pleasure flying.

The upper plane has a span of 48′ 4″, lower plane, 37′ 4″, and a chord of 6′ 3″, stagger of 12″. The gap between the planes is 78″. Fully loaded the machine weighs about 2,500 pounds. Unloaded the weight is about 2,000 pounds.

BOEING AEROPLANE COMPANY

(Armory, Southeast Section)

The Type C-1-F Navy Training Hydro Aeroplane was flown from Hampton Roads, Va., to Rockaway, N. Y., for exhibition at the Aero Show. This machine is equipped with a Curtiss OXX-5 100 H.P. motor. It is an experimental type built for the Navy and has single float instead of the double floats usually employed on Boeing seaplanes.

The top plane is carried on inverted V central struts with no center panel. There is no horizontal stabilizer and the tail flaps are of the balanced type.

The general specifications of the C-1-F are as follows:

Span, both planes	43′ 0″
Chord	5′ 9″
Gap	6′ 0″
Stagger	29¼″
Overall length	24′ 0″
Dihedral	1°
Decalage	2½°
Speed range	36-65 M.P.H.

BURGESS COMPANY

(Armory, Southeast Section)

The Burgess Company is exhibiting a car designed for one of the "C" class twin-motored Navy dirigibles. The car is of streamline form, 40 feet long, 5 feet in maximum diameter, with steel tube outriggers carrying an engine at either side. Overall width of outriggers, 15 feet. Complete weight of car, 4,000 pounds.

Seven passengers may be carried, but the usual crew consists of four. At the front, the coxswain is placed; his duty is to steer the machine from right to left. In the next compartment is the pilot, who operates the valves and controls the vertical movement of the ship, and aft of the pilot the mechanicians controlling the engines. At the rear cockpit is the wireless operator.

The engines are made by the Union Gas Engine Company and are 150 H.P. each. Fuel capacity, 240 gallons; oil, 16 gallons. Four bombs, totaling 1,080 pounds, are carried at the side.

The dirigible for which the car was designed is 192 feet long, 43 feet wide, and 46 feet high; it has a capacity of 180,000 cubic feet. Its high speed is 59 M.P.H., at which speed it has an endurance of 10 hours. Cruising speed, 42 M.P.H.; cruising radius, 12½ hours. Climb, 1,000 feet per minute.

THE CANTILEVER AERO CO.

(Garden, South Section)

The "Christmas Bullet" has caused a great deal of comment in aeronautical circles because of its freedom from struts and wires. It is the first heavier-than-air machine built on the Cantilever truss principle, and is the result of years of painstaking investigations and experiments made by the inventor, Dr. William Whitney Christmas.

The wings of the Christmas Bullet are flexible and resemble true bird form. Because of this yielding principle the machine is absolutely immune from all strain and resistance as are "stiff-wing," parallel-strut machines.

The "Christmas Bullet" has a horsepower of 185 and has flown 197 miles per hour—a world's record.

General specifications of this machine are as follows:

Span, upper plane	28′ 0″
Span, lower plane	12′ 0″
Chord, upper plane	5′ 0″
Chord, lower plane	2′ 6″
Area, upper plane	140 sq. ft.
Area, lower plane	30 sq. ft.
Length overall	21′ 0″
Weight, machine empty	1,820 lbs.
Weight, fully loaded	2,100 lbs.
Minimum speed	50-60 M.P.H.
Maximum speed	185 M.P.H.
Cruising radius	550 miles
Dihedral	minus 17°

A Liberty "6" engine is used, giving 185 H.P. at 1,400 R.P.M.; the machine attains 170 miles at three-quarter throttle.

CAPRONI COMPANY

(Armory, East Section, Center)

The Caproni Company is exhibiting a giant triplane which has been famous since 1915, when it made its first appearance. This triplane has a spread of 130 feet. It is equipped with three 400 H.P. engines, two of them in tractor position at the nose of the fuselage, and one a pusher at the rear of the central nacelle. This machine has climbed to an altitude of 14,000 feet with a ton of useful load and with only two of the engines running. The triplane was used as a bomber and carries a bomb compartment below the lower plane.

CURTISS AEROPLANE & MOTOR CORP.

(Garden, Center)

Curtiss J N 4 D

The J N 4 D Tractor shown by the Curtiss Company is shown with half the cover removed to illustrate the internal construction. All parts of the machine are finely finished and metal parts

Top (left) Curtiss M.F. Flying Boat, (right) Curtiss H.A. Hydroaeroplane. Bottom (left) Curtiss Model K Biplane, (right) Curtiss Flying Boat with Handley Page in the rear

nickel plated. A full description of the J N 4 D was published in the AERIAL AGE WEEKLY.

General specifications are as follows:

Span, upper plane	43′ 7″
Span, lower plane	33′ 11″
Wing chord, both planes	5′ 0″
Gap between planes	5′ 0″
Stagger	16″
Length overall	27′ 4″
Height overall	9′ 10″
Total controlling surfaces	352 sq. ft.
Net weight empty	1,430 lbs.
Gross weight, machine loaded	1,920 lbs.
Useful load	430 lbs.

Motor is model OX 5, 90 H.P. Speed range of 75-45 M.P.H. Climb in 10 minutes 2,000 feet.

The Curtiss M F Flying Boat

The Curtiss M F Flying Boat, a Sportsman's model, is the smallest of the Curtiss boats, a development of the popular "F" boat, carrying two persons side by side.

General specifications are as follows:

Span, upper plane	49′ 9″
Overall length	28′ 10″
Overall height	11′ 9″
Weight, empty	1,796 lbs.
Useful load	636 lbs.
Maximum speed	69 M.P.H.
Minimum speed	45 M.P.H.
Climb in 27 minutes	5,000 ft.
Maximum range	325 miles
Engine, Curtiss OXX	100 H.P.

The Curtiss H-A Hydro

The Curtiss H-A Hydro is a two-place single float seaplane. The upper wing has a dihedral of 3° and the lower plane a cathedral of 1°. Both planes have an incidence of 2°, and a sweepback of 4½°. In official tests by the Navy Department this machine has made a speed of 131.9 miles per hour with a full load. Its climbing speed is 8,500 feet in ten minutes.

The float is 20 feet long, 3 ft. 6 in. wide and 2 ft. 6 in. deep. It has three planing steps.

The horizontal stabilizer is adjustable during flight, within the limits of minus and plus 1°. The machine carries four machine guns; two fixed Marlins and two flexible Lewis.

The engine is a Liberty 12 giving 330 H.P. It is directly connected to a two-bladed propeller 9 ft. 2 in. in diameter, with a 7 ft. 7 in. pitch, or a three-bladed propeller 8 ft. 6 in. in diameter and 7 ft. 6 in. in pitch, depending upon whether speed or quick climb is required.

The general specifications are as follows:

Upper plane	30 ft. 0 in.
Lower plane	30 ft. 0 in.
Cord	72 in.
Maximum gap	70 5/36 in.
Minimum gap	55½ in.
Overall height	10 ft. 7 in.
Overall length	30 ft. 9 in.
Area, upper plane	184.8 sq. ft.
Area, lower plane	170.8 sq. ft.
Total supporting area	390 sq. ft.
Area of each aileron	8.6 sq. ft.
Total aileron area	34.4 sq. ft.
Horizontal stabilizer	25 sq. ft.
Vertical stabilizer	18.9 sq. ft.
Rudder	16.75 sq. ft.

Weights

Weight per sq. ft.	9.35 lbs.
Weight per H.P.	11.5 lbs.
Net weight, machine empty	1,012 lbs.
Weight, full load	2,638 lbs.

Performance

Speed range	62 to 131.9 m.p.h.
Climb	1,000 ft. per minute

DAYTON-WRIGHT AIRPLANE CO.

(Garden, Center)

De Havilland 4

The De Haviland 4 aeroplane exhibited by the Dayton Wright Airplane Company was the first De Haviland 4 battleplane to be built in America, having been completed October 29, 1917, at Dayton, Ohio. This machine has been in continuous service since that time and has been used in 2,500 flying tests of various kinds.

With this machine a distance of about 111,000 miles has been covered in a time of about 1,078 hours. Twenty-eight cross-country trips have been made in it, including Dayton to Washington, Dayton to New York, Dayton to Chicago, Dayton to Cleveland, etc., and in all its career no mishap has ever come to the machine.

The battleplane is exhibited with all its military equipment, including two Marlin machine guns fixed on the front cowling and fired through the propeller at a rate of 750 rounds at 1650 R.P.M. of the engine, and two movable Lewis machine guns at the rear cockpit which fire 650 rounds per minute. The wireless carried has a range of 11 miles to another aeroplane and a receiving radius of 47 miles by a ground station. A camera located to the rear of the observer is worked by means of wind vane. Photographs are taken at the rate of 24 per minute and magazine carries 6 dozen plates.

A full complement of 12 bombs are carried under the lower wings and flare lights for night landing are suspended from the wing tips. Red and green guide lights are carried on the lower plane and a white light is located on the fuselage deck, aft of the gunner.

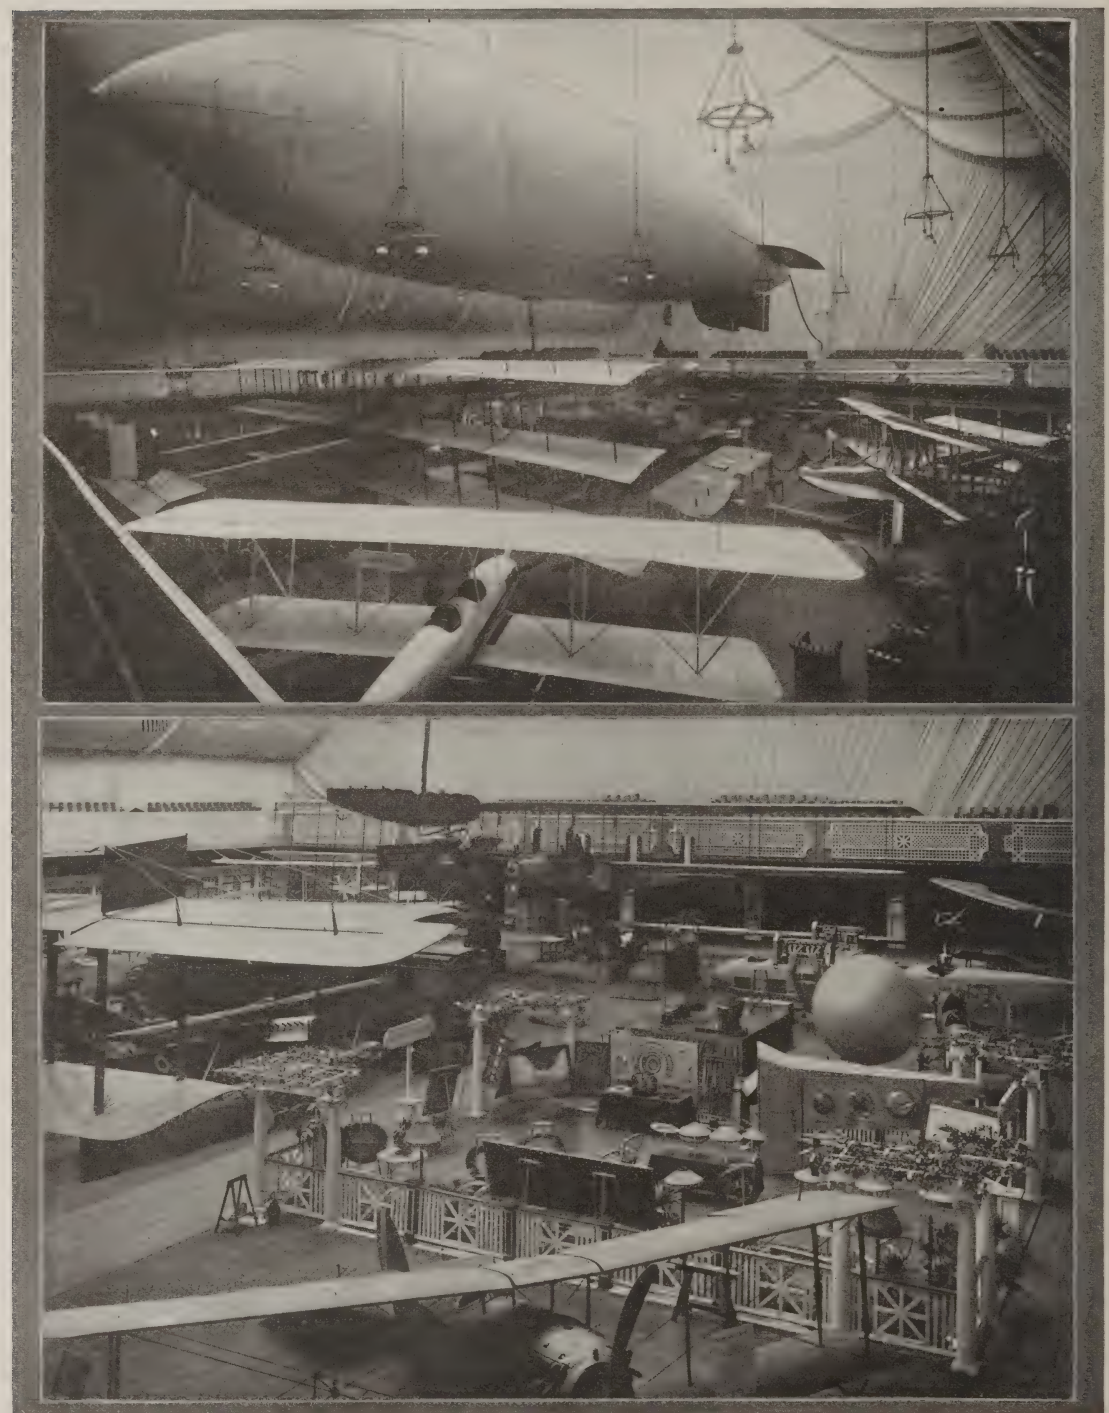
The engine is, of course, one of the first Libertys to be built, and the fact that it is still in such good running condition speaks well for American manufacturing methods.

Dayton-Wright D 4-K

Two of these D 4-K De Havilland machines are being refitted to be used for carrying Government officers on important missions where speed is essential, and the machine is provided with conveniences which make it extremely comfortable, having all the luxurious equipment of the finest automobile. Such appointments as an enclosed weatherproof top, lunch compartments, robe rail, revolving seat and other accessories are provided.

The speed of the D 4-K is about 115 miles an hour near the ground; low speed, 53 miles per hour. The climb is about 10,000 feet in 10 minutes, and the economical radius is four hours.

Dimensions are similar to the D H-4.



The T-4 Messenger

The "Messenger" was designed as a war machine, but after being modified in small details it makes an ideal machine for commercial and sporting purposes. As a war machine its use was to have been in carrying messages from the front lines to headquarters, and in general liaison work.

The machine is exceptionally light, and easy to

Top (left) Curtiss H.A. Seaplane, (right) Thomas-Morse M-B-3 Fighter. Bottom (left) Caproni Triplane, (right) Navy Model F-5-L Flying Boat

Two views in the 69th Regiment Armory, showing the excellent layout of the exhibits. The Naval dirigible presents an imposing appearance, and fills most of the air space. The immense size of the Caproni triplane is accentuated by the numerous ordinary sized machines placed around

Two views of the exhibits in Madison Square Garden. The machines are well set out to show the variety of types, and are accessible for close examination. The Glenn L. Martin Bomber and the Handley Page Biplane present imposing spectacles at the front and rear of the Garden respectively

fly, making it possible to make landings in places that have been heretofore unaccessible. Very rigid flying tests have been made by Mr. Rinehart at Dayton.

The fuselage has absolutely no metal fittings nor tie rods of any sort, strips of veneer being used exclusively for the bracing.

As an example of its strength, the fuselage was supported at either end while 12 men stood at the center.

The machine comes within the means of the average sportsman, for its cost is said to be not much over $2,000.

General Specifications

Span, upper plane	19′ 3″
Span, lower plane	19′ 3″
Chord, both planes	3′ 3 9/16″
Area, upper plane	50 sq. ft.
Area, lower plane	56 sq. ft.
Gap	3′ 8½″
Stagger	0″
Length	17′ 6″
Height	6′ 1″
Angle of incidence	6°
Dihedral of lower plane	3°
Stabilizer incidence	½″
Weight unloaded	476 lbs.
Weight loaded	636 lbs.
Horizontal maximum speed	85 M.P.H.
Landing speed	37 M.P.H.
Climb in 10 minutes	3,000 ft.
Engine, air-cooled De Palma	37 H.P.

The engine is a 4-cylinder air-cooled "V" type manufactured by the De Palma Engine Company of Detroit. Its weight is 3.7 lbs. per H.P. The engine consumes 4 gallons of gasoline per hour and tank has a capacity of 12 gallons. Oil is carried in the crankcase.

GALLAUDET AIRCRAFT CORP.

(Garden, Southwest Corner)

Gallaudet E-L 2 Monoplane

Striking originality in design is shown in the twin-pusher monoplane exhibition by the Gallaudet Aircraft Corporation. Mr. Gallaudet's 1919 Sport Model has a high factor of safety and is easily maintained.

Two stock "Indian" motorcycle engines are located in the nose of the fuselage, connected to a common transverse shaft and resting on the top of the plane, and driving twin pusher propellers on longitudinal shafts driven by bevel gears.

Engines are "oversize" models, giving 20 H.P. each at 2400 R.P.M. Weight, 89 lbs. each. Propellers are 3 bladed (2 bladed propeller on exhibition), 4′ 8″ in diameter and 7′ 0″ in pitch. Propellers run at one-half engine speed, 1200 R.P.M.

The plane has a span of 33′ 0″ and a chord of 4′ 6″. Wing tip ailerons are 7′ 0″ long and 1′ 0″ wide. Wing section, modified R.A.F. No. 15. Dihedral, 178°.

The body is of monocque construction, 3-ply spruce being used. Two seats are provided, side by side, with single stick control.

Tail areas: Fin, 2 sq. ft.; rudder, 4; stabilizer, 12; elevators, 8.

Overall length of machine, 18′ 7″. Special patented true streamline wires brace the wings. For adjustment and dissembling a rod from one cabane to the other permits slackening of the cables and removal of planes without loss of adjustment. Turnbuckles are therefore unnecessary.

Eight gallons of fuel are carried; sufficient for 2 hours.

With full load, a speed of 40-80 M.P.H. is attained. At present the machine weighs 750 lbs., but new features will permit a reduction in weight to 600 lbs.

Gallaudet D-4 Bomber

The Gallaudet D-4 Light Bomber was described in AERIAL AGE WEEKLY in the issue of January 6. This machine is powered with a Liberty motor driving a pusher propeller attached to a ring surrounding the fuselage. The D-4 actually made an official record of 110 knots (126.7 miles) an hour over a measured course. Other performance figures obtained by actual flight tests are as follows:

High speed	126 M.P.H.
Slow speed	42.6 M.P.H.
Slowest getaway	46 M.P.H.
Climb in 2 minutes	2,100 ft.

AERIAL AGE WEEKLY

(Elevated Platform—Garden and 69th Armory)

AERIAL AGE holds many distinctions, among them (1) that of having been the first publication in the United States to urge the creation of the Council of National Defense and having continued the campaign of national education which resulted fifteen months later in the creation of the Council and, subsequently, the creation of the Aircraft Production Board.

(2) That of having been the first publication to donate advertising space for the Mobilization of Industries, for Recruiting and for the Liberty Loans.

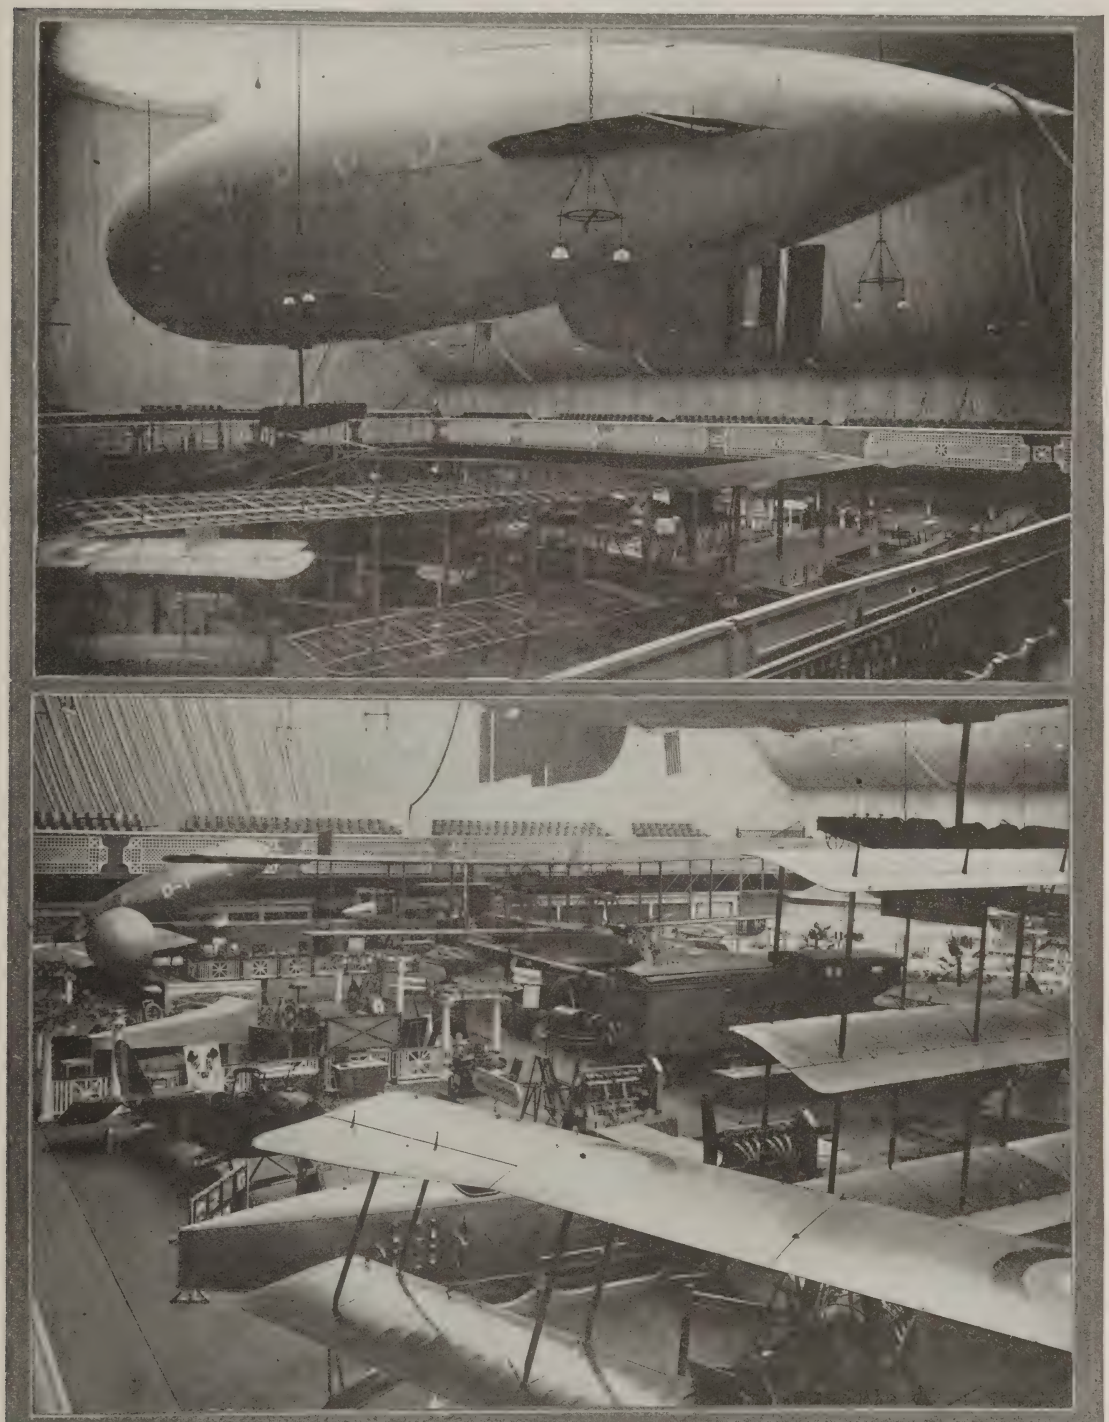
(3) That of publishing twice as much technical material and trade and news items as any other aeronautic publication.

(4) That of publishing weekly the complete official reports of the Army and Navy Air Services together with articles by the recognized authorities on Military and Navay aeronautics, thereby insuring to the reader a more complete representation of Army and Navy aeronautics than is afforded by any other publication in the United States.

(5) That of always publishing articles on technical developments written by authorities on the subject, refusing the purely theoretical essays of men who have not had actual experience in original research, in the factory or in the field, whose theories only lead to costly failures to those who adopt them.

(6) The distinction of having carried a larger amount of advertising in 1918 than any other publication.

There are many other distinctions, but the above explains how AERIAL AGE became the National Technical Engineering and Trade Authority.



FLYING MAGAZINE

(Elevated Platform—Garden and 69th Armory)

Official publication Aero Club of America, Aerial League of America, Aero Club of Illinois, Aero Cub of Pennsylvania, Aero Club of New England, Aero Cub of Minneapolis, Pan-American Aeronautic Federation, National Special Aid Society, National Aerial Coast Patrol Commission, The Woman's Naval Service.

Top (left) Dayton-Wright D 4-K, (right) Curtiss Hydroplane. Bottom (left) Dayton T4 Messenger, (right) Ansaldo A1

Two views in the 69th Regiment Armory. The upper picture shows the large Naval flying boat, which attracts wide attention, and which being half stripped, half covered, amazes the spectators by showing them the enormous amount of detail in aircraft construction

THE L-W-F COMPANY

(Armory, Northeast Side)

The L-W-F Model V Tractor was described in AERIAL AGE WEEKLY of May 22, 1916. This machine, equipped with 125 H.P. Thomas engine, is convertible from a land machine to a hydro. The machine exhibited at the show has twin floats.

The L-W-F Company also exhibits one of the H S 1 L Coast Patrol Flying Boats with a 350 H.P. Liberty engine. The machine has a span of 62' and chord of 6' 3" and the total wing area is 653' including ailerons. Overall length is 38' 6" and overall height is 14' 7". The hull weighs 1,265 lbs. Gross weight 5,900 lbs. and weight empty 4,810 lbs. Fuel and oil 750 lbs. and crew 360 lbs.

Machine has a maximum speed of 91 M.P.H. and a low speed of 53 M.P.H. Climb in 10 minutes is 3,000 feet.

L-W-F Model G-2 Fighter

Model G-2 is a two place armored fighter carrying 7 machine guns and 4 bombs. Guns are arranged to be fired downward through an opening in the bottom of the fuselage.

The main specifications of the Model G-2 are as follows:

Dimensions

Span overall	41' 7½"
Chord, both planes	80"
Gap between planes	74"
Stagger	7⅛"
Length overall	29' 1¼"
Height overall	9' 4⅜"

Weights (pounds)

Weight, light (fighter)	2,675.5
Total, full load (fighter)	4,023.
Weight, light (bomber)	2,675.5
Total, full load (bomber)	4,879.5

Areas (sq. ft.)

Total, supporting surface and ailerons	515.54
Net area of main planes	465.46
Upper planes, with ailerons	268.78
Lower planes	246.76
Stabilizer	29.15
Elevators	27.70
Fin	5.21
Rudder	12.65

Performance (Fighter)

Speed at 10,000 ft.	130 M.P.H.
Speed at low altitude	138 M.P.H.
Low speed	50 M.P.H.
Climb to 10,000 ft.	9 min. 18 sec.
Endurance at full speed	4 hours

The engine is a Liberty, giving 435 H.P. at 1700 R.P.M. Propeller, 9' 7" diameter; 7.38 ft. pitch.

THE GLENN L. MARTIN CO.

(Garden, Center, West)

The Martin Bomber

The Martin Twin Engine Bomber in its official test at Wilbur Wright Field, Fairfield, Ohio, has excelled any other record for a similar bomber either here or abroad.

A speed of 118.5 M.P.H. was made on the first trial with full bombing load. The climbing time with full bombing load was 10,000 feet in 15 minutes and a service ceiling of 16,500 feet was attained. As a military machine the Martin Twin is built to fill requirements of a night bomber, day bomber, long distance photographer, or a gun machine. As a night bomber it is equipped with 3 Lewis guns, 1,500 pounds of bombs and 1,000 rounds of ammunition. A radio telephone set is carried on all four types. Fuel capacity sufficient for 6 hours. Full power at 1,500 feet.

As a day bomber 2 additional guns are carried and the bomb capacity cut to 1,000 pounds. The Martin Twin is easily adaptable to commercial uses which are now practical; they are mail and express carrying, transportation of passengers, and aerial map and survey work. As an example of its capacity, 12 passengers or a load of merchandise weighing a ton may be carried.

General dimensions are as follows:

Span, both planes	71' 5"
Chord, both planes	7' 10"
Gap	8' 6"
Overall length	46' 0"
Overall height	14' 7"

With a ton of useful load speed of 100 to 150 M.P.H. is made. Two 400 H.P. Liberty engines are used.

PACKARD MOTOR CAR CO.

The Packard Aeroplane

(Garden, North, Center)

The Packard two-place tractor was designed around and made a complete unit with the Model 1-A-744 Packard Aviation Engine. This machine will make about 100 M.P.H. with full load, on account of its light weight and clean-cut design, and yet its landing speed is as low as the average training aeroplane.

Fast cross-country trips are made possible in this ship, with the ability to land in relatively small fields. The general specifications are as follows:

Power Plant

Packard 8 cylinder 160 H.P. at 1,525 R.P.M. Weight, complete with hub, starter, battery and engine water, 585 lbs. Fuel consumption, .50 to .54 lbs. per H.P. hour at sea level.

Weights, Areas, etc.

Area, main planes	387 sq. ft.
Weight, machine empty	1,520 lbs.
Normal flying weight	2,167 lbs.
Weight, lbs. per H.P.	13.5 lbs.
Wing loading, per sq. ft.	5.6 lbs.
Permissible extra luggage	100 lbs.

Performance (estimated)

Altitude (feet)	Speed (M.P.H.)	Time of Climb (minutes)	Fuel range (hrs.)
0	102	0	2.5
5,000	100.5	7.5	3
10,000	98	18.1	3.5
15,000	90.5	34.5	4

Absolute ceiling, 19,500 feet.

STANDARD AERO CORPORATION

Handley Page Bomber

(Garden Rear Center; Armory, S-W Side)

The American built Handley Page shown at the Garden is similar to the British, except that Liberty "12" 400 H.P. engines are employed in the former and the Rolls-Royce or Sunbeam in the latter. Accommodations are made for one pilot and two or three gunners and an observer, who operates the bomb dropping device. Two guns are located at the top of the fuselage and a third is arranged to fire through an opening in the under side of the fuselage, and a pair of flexible Lewis machine guns is operated at the forward end of the fuselage. One gunner may have charge of all rear guns although usually two gunners man them.

James Ex. Kepperley
Mr Fay L. Faucett
Mr Elmer A. Sperry
Major H. C. Mainon
Sketches made from life at AERO SHOW by Norman E. Jewett 1919

The general dimensions of this machine are as follows:

Span, upper plane	100′ 0″
Span, lower plane	70′ 0″
Chord, both planes	10′ 0″
Gap between planes	11′ 0″
Length overall	62′10″
Height overall at overhang cabane	22′ 0″
Height overall at center panel	17′ 6″
Width, wings folded	31′ 0″
Machine empty	1,566 lbs.
Machine loaded	14,300 lbs.

Each of the two engines give 400 H.P., at 1,625 R.P.M.

Speed at ground, 92 M.P.H.

The "E-4" Mail Aeroplane

(69th Regiment Armory)

The "E-4" Mail Plane, built by the Standard Aero Corporation, is particularly adaptable to the work of carrying mail because of the special features of its design. The machine exhibited has seen considerable service, having been brought directly to the show after completing one of its regular mail carrying trips.

The engine is a Wright-Martin Model I Hispano-Suiza, giving 150 H.P. at 1,500 R.P.M., and 170 H.P. at 1,700 R.P.M. The model I is an 8 cylinder V type with a bore of 120 mm. (4.724″) and a stroke of 130 mm. (5.118″).

General specifications of the "E-4" are as follows:

Span, upper plane	31′ 4¾″
Span, upper plane with overhang	39′ 9¾″
Span, lower plane	31′ 4¾″
Chord, both planes	6′ 0″
Gap between planes	5′ 6″
Stagger	5¼″
Length overall	26′ 2″
Height overall	10′ 10 3/16″
Machine empty	1,566 lbs.
Machine loaded	2,400 lbs.
Machine loaded with overhang	2,450 lbs.
Stalling speed	50 M.P.H.
Gliding angle	1 to 8
Dihedral	3° or 1¾°

The speed at ground is 100 M.P.H.

THE THOMAS-MORSE AIRCRAFT CORPORATION

(Garden, North Section, Center)

Four aeroplanes shown by the Thomas-Morse Company: the Type S-6, S-7, S4-C Scout and the M-B-3 Fighter.

The M-B-3 Fighter is equipped with a 300 H.P. Hispano-Suiza Engine. It is a single seater, and is said to be the fastest climbing aeroplane in the world.

The S4-C is an 80 H.P. Le Rhone Scout, used for advanced training. It has been used at most of the army training schools throughout the United States.

The S-6 is a Tandem 2 seater, very similar to the S4-C in general appearance. With an 80 H.P. Le Rhone, this machine has a speed range of 35-105 M.P.H. In 10 minutes, its climb is 7,800 feet.

The S-7 is a side by side tractor with an 80 H.P. Le Rhone engine. The side by side seating makes it especially desirable for pleasure flying. The cockpit contains numerous comforts and conveniences.

The principal dimensions and specifications of the S-7 are as follows:

Span, both planes	32′
Chord, both planes	5′ 6″
Incidence angle	1½°
Gap between planes	4′ 6¼″
Overall length	21′ 6″
Stagger	34% of Chord
Weight, loaded	1,480 lbs.
Weight per square foot	4.25 lbs.
Climb in 10 minutes	6,700 feet
Maximum speed	90 M.P.H.
Minimum speed	35 M.P.H.
Low flying speed	40 M.P.H.

THE UNITED AIRCRAFT ENGINEERING CORPORATION

(Armory, N-W Section)

This Company is showing a Canadian-Curtiss training plane, such as used by the Royal Flying Corps for instruction in Canada and England.

A number of Curtiss OX-5 100 H.P. engines are also on display, together with other equipment, which the Company has purchased from the Imperial Munitions Board of Canada.

UNITED STATES ARMY

Langley Experimental Flying Machine

(Garden, North-rear)

The model of the Langley aeroplane is a copy of the original Langley Flying Machine, which is now in the United States National Museum at Washington, D. C. This machine made the first successful flight by heavier-than-air machine driven by its own power. The machine was launched May 6, 1896, at Quantico, Va. It rose to a height of 70 to 100 feet and travelled half a mile at 20 to 25 M.P.H., with propellers revolving at 1,500 R.P.M.

The total weight of the machine is 26 pounds. It is driven by a single cylinder engine, using gasoline as fuel.

Foreign Aeroplanes

Among the foreign aeroplanes sent to the Aero Show by the War Department are the French Spad (*rear, Garden*), French Nieuport (*Front, S. W. cor. Garden*), British SEV and a German Albatross DII (*center, Armory*).

The Spad is a single seater scout with a Hispano-Suiza Engine.

The Nieuport Single Seater is equipped with a rotary Gnome Engine.

The SEV, which was put into limited production in the United States, has a Hispano-Suiza Engine.

The Albatross Scout was one of Germany's best fighters. It has a Mercedes Engine.

U. S. Army

In addition to exhibiting military aeroplanes the War Department is featuring the recent developments of radio telephony as a part of their exhibit. Under the supervision of Lieutenants Woolfolk, Shangraw and Adams, visitors are permitted to "listen-in" while aeroplanes above are being directed by voice command. It is thereby possible to hear the orders, just as the aviator in the plane hears them. An SCR-67 set is used for radio-telephone transmission and reception. Other sets on view are the SCR-57, an interphone for communication between aeroplane occupants; SCR-73, the 200 watt spark set, equipped with rotary gap, which was used for the direction of artillery fire with remarkable success; SCR-72, the two step amplifier, which increases a faint signal to one of extreme loudness; the SCR-81, a direction finding outfit, and numerous others.

On the balcony of the Garden, the Department of Military Aeronautics is exhibiting some remarkable photographic maps or "mosaics" which attracted general attention. There are also photographs showing the work of the military photographer, taking photographs, developing, printing, mounting in mosaics, and comparing them with other maps. A mosaic covering the territory between Fort Sill and Wichita on a scale of 10,000 to 1, having an area of over 35 square feet is an interesting example of the work done by the military photographer.

UNITED STATES NAVY DEPARTMENT

(Armory, West Center)

The F-5-L Flying Boat

The F-5-L, constructed by the Naval Aircraft Factory at Philadelphia, has a span of 107 feet, wing chord of 8 feet, and an overall length of 50 feet.

Two 400 H.P. Liberty Engines are used, connected to tractor propellers 10′ 6″ in diameter. 500 gallons of gasoline are carried, sufficient for a duration of 10 hours at full speed, near sea level, and a speed of 102 M.P.H. is maintained.

Fully loaded the machine weighs 14,000 lbs. This weight includes a crew of 5 men; 1 Davis and 4 Lewis machine guns; 4 230 lb. bombs; radio apparatus; telephone system with 6 stations; carrier pigeons; and 500 gallons of gasoline.

The machine is exhibited with one half covered and the other half exposed to show the interior construction.

In the making of this machine there are 6,000 distinct pieces of wood, 50,000 wood screws, 46,000 nails, braces and tacks, and 4,500 square feet of cotton fabric. The hull requires 600 square feet of veneer. The 250 pieces of steel tubing total 1,000 feet in length. 5000 feet of wire and cable, 500 turnbuckles, 1,500 each of bolts, nuts, and washers, and 1,000 metal fittings are necessary in the construction of this flying boat.

Navy M-2 Baby Seaplane

The M-2 Seaplane designed by the Navy Department and built by Grover Cleveland Loening, was to have been used for submarine patrol work. It is the smallest seaplane ever built, and its size has gained for it the name of "molecule." It is easily set up and, occupying so little space, can be stored aboard a submarine.

The machine is a tractor monoplane with twin floats. The plane has a span of 19′, a chord of 4′, and a total wing area of only 72 square feet. The wing section is a modified R.A.F. 15. Overall length of machine 13′.

The floats are 10 feet long and weigh 16 lbs. each. They are constructed of sheet aluminum with welded seams. The interior of the floats is coated with glue and outside is not painted but coated with oil. Experiments have proven this practice to be most efficient in preventing corrosion. Mr. Loening's experiments have proven that paint applied to aluminum causes a corrosive galvanic action. Floats have exceptional reserve buoyancy; with machine at rest on the water it is impossible to overturn machine by standing on the wings near the tips or by standing on the rear of the fuselage.

The engine is a 3 cylinder Lawrance 60 H.P. air cooled engine, driving a 6′ 6″ propeller with a 5′ pitch. 12 gallons of gasoline and 1 gallon of oil are carried, sufficient for 2 hours' flight. Fully loaded with pilot and fuel the complete machine weighs but 500 pounds. The maximum speed is about 100 M.P.H., and the low speed is 50 M.P.H.

Helium Filled Model Airship

The model dirigible exhibited by the Navy Department is inflated with Helium, which would have cost one million dollars a year ago, and which now can be produced for about $100. It is through the wonderful discovery of Helium that the dirigible balloon will make great development. Its cost is at present about 10 cents per cubic foot and later it will cost even less. The remarkable feature, however, is the fact that it is not inflammable, and therefore one of the greatest drawbacks of lighter-than-air craft is overcome.

Another item that is of interest is the fact that this model dirigible, 32′ long and 7′ in diameter, contains more Helium than has ever been placed in an envelope of any kind. In spite of the chemical process that makes it non-inflammable, Helium contains 85% of the lifting power of Hydrogen.

The army and navy controls the entire sources of supply of this gas. Stations in Kansas and near Fort Worth, Texas, will soon produce about 2 million feet of Helium per month.

Astra-Torres Dirigible

The dirigible car shown by the Navy Department is from a ship of the "Astra-Torres" type. The airship was built by the French in 1916 and turned over to the Americans in March, 1918, at Paimboeuf, France, the American Naval Station commanded by Commander L. H. Marfield, U.S.N. It was used until November, 1918, for coast patrol on the west coast of France.

The car is 45 feet long, 6 feet wide and 7 feet high. The envelope (which is not exhibited) is 221 feet long and 47 feet in diameter, having a capacity of 252,000 cubic feet. Speed, 45.5 miles per hour. With a crew of Americans, this ship has stayed aloft for 25 hours 40 minutes. At its cruising speed of 45.5 miles, the endurance is 10 hours.

The car accommodates a crew of 12. At the front, the pilot controls the side-to-side movements of the ship. Behind him is the bridge from which the altitude and trim are controlled by a pilot, and the engines controlled by the Commanding Officer. Upon the bridge are numerous instruments for navigation. Below and aft of the bridge is the chart room, about 6 feet square, also used as a dining room. Next is the blower motors and blowers for maintaining the pressure and trim of the envelope.

A passageway runs through the center of the car, and four fuel tanks and two water ballast tanks are located at either side. Aft of the tanks are the bomb racks, holding four 150 lb. bombs, and at the stern is the radio room. Two 150 H.P. Renault engines with two-bladed tractor propellers are used. They are placed on outriggers. Two Lewis machine guns are carried.

This ship is one of several large dirigibles purchased by the United States Navy and brought to this country for the purpose of development.

U. S. Navy

In addition to the seaplanes and dirigibles exhibited by the Navy, which are described under another heading, there can be seen at the Navy booths in the Armory almost every type of aerial ordnance used during the war, including the Davis non-recoil gun, two captured German Spandau machine guns, etc. A great many aeroplane motors of various types, manufactured for the Navy, are mounted on test stands, in the same manner as they can be found in Navy instruction schools.

Several types of radio equipment are in evidence, developed by the Bureau of Steam Engineering. On the dirigible car of the Astra-Torres type, described under another section, is a French radio set, which saw considerable service during the war.

Another feature of interest is the pigeon loft, containing thirty pigeons which were used to carry distress signals from pilots downed at sea. Some of these pigeons had war records consisting of more than six months' overseas service.

Numerous excellent photographs supplement the complete exhibit, showing all phases of the work of the naval aeronaut.

The Ansaldo Exhibits at the Aeroplane Show

IN the center of the 69th Regiment Armory the firm of Gio Ansaldo & Co., of Genoa, Italy, exhibits two sister machines, which represent the most original and advanced developments in Italian aviation, and are the more interesting because of their glorious achievements in the war. They are the S. V. A. and the Ausaldo I, the latter better known by its nickname of "Balilla," a popular Italian hero.

Designers of the S. V. A.

The first of these machines to appear was the S. V. A. It was designed by two officers of the Technical Branch, Italian Aviation Service, Colonels Savoia and Verdusio, whose initials give the first two letters to the name of the machine.

The builder was the great Ansaldo Company of Genoa, a concern having over 150 million dollars capital and which, during the war, turned all its activities to the manufacture of guns, ammunition, ships, all kinds of war materials and machinery—including the most modern one, the aeroplane. And Ausaldo's initial accounts for the third letter in the name.

Aim of the Designers

The S. V. A. was designed with the determination of embodying the latest and soundest prin-

MISCELLANEOUS EXHIBITS

AERO INSTRUMENT CORPORATION

(*Garden, Balcony, Right*)

The Aero Instrument Corporation of New York City are manufacturers of accurate aero altimeters, clocks and temperature-recording barometers and speedometers. The characteristic feature of this altimeter is its supreme accuracy, which is obtained by eliminating the chain drive, now almost universally used. This is replaced with three ingeniously designed cams so arranged as to cause the indicating needle to move the same distance per thousand feet at all altitudes, eliminating the cramped scale at the higher altitudes. This company manufactures altimeters reading as high as 35,000 feet, with extremely high accuracy.

The chief engineer of this company, who designed this altimeter, is Mr. Albert Bourrieu, formerly chief engineer of the Companie Francaise, famous makers of electric meters and precision instruments and chief of fabrication of the Electric Light Company of Paris. Mr. Bourrieu is well known as the inventor of the taximeter, universally used as the fare-recording device on taxicabs.

An extremely delicate indicating recording barometer and altimeter, which the Aero Instrument Company has brought out, gives the aviator's performance without possibility of error. The clockwork which operates the device is readily adjusted to turn the recording cylinder around in any length of time between one hour and twenty-four hours. The construction of the instrument does not permit the appearance of a magnetic field through its parts to affect the accuracy of the readings.

ACIERAL PRODUCTS CO.

(*Garden, Space* 123-124)

The Acieral Products Company is displaying its light weight pistons, which are 2½ times lighter than cast iron and have more than double its heat conductivity. The Acieral Casting composition is said to overcome the usual imperfection of sand holes, porosity, shrinkage cracks and permits of high polish finish.

AIRCRAFT ENGINEERING CORPORATION

(*Garden, Space* 506)

The Aircraft Engineering Corporation of New York's exhibit consist of models and photographs of the ACE plane, designed for the use of the aerial sportsmen, to sell at a price of $2,500. The enthusiasm with which this exhibit is greeted serves as a barometer of the desire of people for a small low-cost flying machine. Demonstrations are being given daily at the aerodrome at Central Park, Long Island, which emphasizes the safety and simplicity of the machine. The plane lands at a speed of only 30 miles per hour, and owing to its light weight and construction, comes to a stop within 50 feet of where it strikes the ground. Its fuel consumption is only four gallons per hour, while its flying speed is sixty miles an hour. Its simple and rigid construction makes it one of the pioneer machines for the civilian aeronautic enthusiast.

AJAX AUTO AND AERO SHEET METAL CO.

(*Garden, Space* 612-613)

The Ajax Auto and Aero Sheet Metal Co. of New York are exhibiting several models of their honeycomb radiators, which have been used on L. W. F., Aeromarine and Standard aeroplanes. The manufacturers state that the high cooling efficiency of their radiators is due to the fact that all four sides of the water tubes contribute to the cooling of the water within.

AMERICAN BALSA CO.

(*Armory, Space* 631-634)

The American Balsa Co. of New York City, by treating balsa, a wood imported from Costa Rica and Panama, with the Marr process, is able to produce a wood having a weight only one-fourth that of spruce yet possessing one-half of its strength. It is especially adapted for instrument boards, fuselage beams, flooring, seats and other parts not requiring great strength. The extreme bouyancy of balsa was utilized in the construction of life rafts for transports. A pair of balanced scales show that 12½ times the cubic quantity of balsa were required to counterbalance a unit block of iron.

AMERICAN BOSCH MAGNETO CO.

(*Garden, Space* 201-206)

The American Bosch Magneto Co. are exhibiting their complete line of magnetos ranging from 1-cylinder to 18-cylinder equipments, mounted on display stands with hand-operated cranks. Although this company's production was largely confined to magnetos for motor trucks and cars, tanks and other vehicles, they are prepared to manufacture magnetos for aircraft motors of all sizes.

AMERICAN PROPELLER & MFG. CO.

(*Garden, Space* 108-109)

The extensive facilities of the American Propeller Co., of Baltimore, Md., were fully utilized in the war program. This company manufactured all types of propellers, from the small air-fan used in driving generators for heating, lighting and radio, to single, two, three and four-blade air-screws for fighting and bombing planes. This company's exhibit consists of various types of propellers made for the government program.

A-C SPARK PLUGS

(*Garden, Space* 514)

When the armistice was signed, the Champion Ignition Company, makers of A-C plugs, were producing 40,000 plugs daily for aircraft alone. Besides this, this firm was making spark plugs for ordnance tanks and trucks. Every standardized Class "B" truck was originally equipped with A-C Titan plugs.

When America entered the war spark plug production was not sufficient for our program. Mica insulated plugs were being used abroad on French, British and Italian planes, but the individual skill required in the manufacture of such plugs made quantity production difficult. Plugs made of wrapped mica and with mica washers, moreover, are not easily duplicated. Only a small percentage of them pass inspection.

To fill the need, it was necessary to produce a porcelain plug, which would be adapted to quantity production. Working in conjunction with engineers of other companies, the Champion Ignition Company collaborated in the development and design of a porcelain spark plug which would withstand the high temperatures to which an aviation motor is subjected. The results obtained in tests of these plugs as compared with those of foreign make reflected most favorably on American design and manufacture.

The BRISTOL CO.

(*Garden, Space* 333)

The Bristol Co. is manufacturer of high grade gauges and measuring instruments. Their exhibit consists of several of their air speed indicators and water ballast gauges, which indicate the amount in inches of water remaining in the ballast tank, as used on dirigibles.

BUDD WHEEL CO.

(*Armory, Space* 607-609)

Wire wheels for aircraft of all sizes and types for large and small planes are being exhibited by the Budd Wheel Company. Strength, simplicity and rigidity of construction are outstanding features of the design of their products.

COLD LIGHT MFG. CO.

(*Garden, Space* 520)

The Cold Light Company of New York City, manufacturers of "Marvelite" luminous paints, are exhibiting various indicating devices to which their luminous paint had been applied, including compasses, clocks, tachometers and gauges. Charts, illustrating the process of manufacture from the mine to the finished product, vividly depict the great engineering skill required to produce a truly luminous paint. This material is a mixture of a very small amount of radium with a base which is rendered luminous by the action of the radium. Marvelite is truly a radioactive material and is not dependent on phosphorescence for its luminosity. It therefore remains luminous indefinitely and does not lose its brilliance after short radiation in darkness. Phosphorescent materials may appear brilliant for a short time in the dark, but they lose their luminosity when the light absorbed during daylight has been radiated.

COLLEGE OF THE CITY OF NEW YORK

(*Garden, Balcony, Center*)

The College of the City of New York is conducting several courses for aeronautic mechanics and engineers, full information regarding which is published elsewhere in this issue. The school has $85,000 worth of aeronautic equipment.

CONNECTICUT AIRCRAFT CO.

(*Garden, Space* 127-131)

The Connecticut Aircraft Company of New Haven, Conn., are displaying several detailed models of the various types of lighter-than-air ships which they have manufactured. They are also exhibiting a model of a huge passenger dirigible of 300,000 cubic foot gas capacity, to be propelled by two 400-horsepower motors, to carry twenty passengers. This company manufactured Type "R" kite balloons, U Type dirigibles and the "Solo" free balloon having a capacity of 18,000 cubic feet.

DAYTON ELECTRICAL ENGINEERING LABORATORIES

(*Garden, Space* 517-519)

A complete line of Delco Ignition Products, both of Delco design and those made to Government specifications are being exhibited at the Delco booth. The Delco Company has been manufacturing generator-battery-distributor ignition systems for the automobile industry in huge quantities, so that their design and manufacturing experience were of great value in securing adequate production for aviation purposes during the war. Every Liberty motor was equipped with ignition of this type, and the Delco Company contributed largely to national production. A complete Liberty "12" ignition system is on display as manufactured by this company to Government specifications.

Delco equipment for the Packard aviation engine of 8 and 12 cylinder type and for the Lorraine-Didietrich motor, as manufactured for the French Government, are to be seen at the Delco booth.

For those interested in testing equipment there is a complete ignition inspector's outfit, including apparatus to determine the angularity of spark occurrence.

DAYTON WIRE WHEEL CO.

(*Armory, Space* 614-615)

The Dayton Wire Wheel Company are among the foremost manufacturers of wire wheels for motor cars and aeroplanes, and they have produced wheels in large quantities for the aircraft industry for training and war planes. Their exhibit includes wheels for the lightest and heaviest aircraft of both single and twin type.

DETROIT ACCESSORIES CO.

(*Garden, Space* 501)

This company's contribution to the aircraft industry consists largely of motor pump parts of light weight and great strength. Their exhibit includes motor pumps complete and dissembled.

DODGE MANUFACTURING CO.

(*Garden Exhibition Hall*)

The Dodge Manufacturing Company's exhibit shows laminated plywood, which is used in fuselage construction, in small and large sheets, from the thin, light material used in fuselage construction to the large multiple-ply planks from which the stouter parts are made. Wing-ribs, struts, spars, engine bearers and all the essential parts of the aeroplane are shown, as made for actual machines.

The greater part of the structural framework and body covering of the DeHaviland-4 planes were made of plywood and a complete fuselage of this company's construction was on view. Trussed members of laminated plywood have replaced the metallic aluminum for the framework of rigid dirigibles, the use of the noninflammable hydrogen having eliminated the danger of fire.

The successful use of pylwood helped to solve the spruce problem, since any available wood may be used without long-distance transport, delays in seasoning, and difficulties from twisting and winding grain.

DOEHLER DIE CASTINGS CO.

(*Garden, Space* 207-208)

The Doehler Die Castings Co. of Brooklyn and Toledo are displaying numerous high-grade aluminum and alloy castings, which they have turned out in large quantities for the aircraft industry. Parts for Liberty and Curtiss motors, magneto housings, parts for Lewis guns, including the spiral guide for bullets in the magazine, camshaft and crankshaft bearings and scores of others are on view. This company has developed a process of babbitting on aluminum, thus permitting great strength of bearing surface without undue weight. This babbitt-lined aluminum bearing, known by the trade name of "Do-Lite," is used on Curtiss V-type 210-horsepower motors, the King-Bugatti motor, manufactured by the Duesenberg Motors Corporation, and the Liberty motors, as well as by several motor car manufacturers. This company makes all types of aluminum, brass, bronze and white metal for quantity production.

DUDLEY LEE TENNY CO.

(*Garden, Space* 334)

This company is exhibiting a reinforced steel propeller which has just been brought on the market. It is claimed by the manufacturers that this propeller can be produced in any strength and weight, that it will not flutter owing to the heavy leading edge and is unaffected by climatic conditions.

DUESENBERG MOTORS CORPORATION

(*Armory, Space* 648-655)

The Duesenberg Model H motor, manufactured by this company and described in detail in the January 27 issue of AERIAL AGE WEEKLY, forms the chief center of interest at the booth of the Duesenberg Motors Corporation, of New Brunswick, N. J. This is a 16-cylinder motor, developing 850 horsepower. Another motor which this company manufactured for war purposes is the King-Bugatti motor, also described in detail in AERIAL AGE WEEKLY on February 10. Several other motors, including the Model A, 4-cylinder, 150-horsepower motors, are being exhibited by this company.

EASTMAN KODAK COMPANY

(*Garden, Space* 511)

The Eastman Kodak Company, of Rochester, N. Y., is displaying a complete line of aeronautic cameras, suitable for military and mapping purposes. An interesting feature of their exhibit is the "photographic gun," used to train aviators in aerial marksmanship, which is mounted on the standard gun ring. The aviator, instead of firing bullets, snaps photographs of his mark and upon development of the film a record is obtained of the number of bulls'-eyes obtained and the accuracy of aim. This device has resulted in the saving of considerable ammunition for training purposes.

The cameras include hand-held types and types requiring special mounting, for both roll films and plates. Simplicity of operation, convenience of loading and ease in aiming and handling is a feature of every camera manufactured by the Eastman Company. Their extensive experience and research in orthochromatic and panchromatic photography, in the manufacture of lenses and shutters, in all types of roll films and plates, combined with the information which was placed at the disposal of our air services by our allies, resulted in the development of aerial photography and apparatus to a very high plane.

The Model A-1 camera, having a capacity of twelve 4x5 plates or Eastman cut film, is a type which will undoubtedly find favor among aerial photographers. It is equipped with a 10-inch Hawk Eye lens having a fixed aperture of f4.5 and a shutter capable of adjustment through a speed range of 1/120 to 1/450 of a second. In common with all Eastman aerial cameras, a safety shutter as a protection to mist, fog and dirt is provided, which opens only when the exposure is made. The loading is extremely simple and a new magazine can be attached in an instant. The camera is sighted directly at the object and a slight pressure of the thumb lever release opens the safety shutter, exposes the lens and makes the exposure. One short quick turn of a lever advances the film and resets the shutter.

Two types of cameras for photographic mapping, one hand mounted and the other for fixed mounting on a special rack, make the production of photographic maps almost automatic. Flying at definite altitudes, so that the negatives are made to scale, it is possible to fit the prints or enlargements together with sufficient accuracy to produce photographic maps of considerable accuracy over wide areas. A photographic map of the city of Rochester made in two and a half hours shows how effectively, speedily and accurately photographic mapping can be done.

EDISON ELECTRIC APPLIANCE CO.

(*Armory, Left Side*)

The Edison Electric Appliance Co., makers of the famous Hot Point products, have filled large Government contracts for aviators' electrically heated clothing. An interesting part of their exhibit is an aviator's high altitude flying uniform with helmet, electrically heated gloves and pads. Such equipment is necessary for all high altitude flying, where low temperatures are encountered at all seasons of the year.

EDSTROM MACHINE CO.

(*Armory, Left Front*)

The Edstrom Machine Co. are displaying one of their wire-wrapping machines, which have been officially inspected by the Navy Department and the Department of Military Aeronautics. By means of this machine, operated by a crew of two men, a neat and strong wrap can be made in 45 seconds, which is of better workmanship than can be produced by the most skilled hand labor. In official tests the machine wrap stood 100 per cent. of the tensile strength of the wire on which it was made, amounting to more than 4,200 pounds. A test of this wrap, without soldering, resulted in nine out of ten wraps withstanding the full tensile strength of the wire, the tenth giving way at 71 per cent.

One aircraft manufacturer stated that this machine enabled two men to turn out as many wraps of a much better quality as could be obtained by manual wrapping of twelve to twenty men.

EMPIRE ART METAL CO.

(*Armory, Space* 603-606)

This company has developed a wing structure made entirely of metal, having the same weight as wood, with considerably increased strength. A factor of safety of nine is obtained. These wings have been used on Curtiss JN4B training planes with great success and a pair of these wings as manufactured on Government contract, together with rudders, and wings for use on C-1 planes with a carrying load of 39 pounds per square foot are on exhibition. In addition to increased strength the use of metal adapts itself to quantity production and assembly by only moderately skilled personnel.

ERICSSON MFG. CO.

(*Garden, Space* 301-302)

The Ericsson Mfg. Co., of Buffalo, N. Y., makers of the famous "Berling" magnetos, are showing their complete line of magnetos, including the D-83 for Curtiss OX-2 motors, the D-81 for Curtiss OX-5 motors and the J-12 type, which is being developed for the new Curtiss 12-cylinder motor, now still in the experimental stage.

GENERAL ORDNANCE CO.

(*Garden, Space* 509)

The General Ordnance Company are exhibiting their non-recoil heavy aircraft gun, which has had extensive use during the war. The gun overcomes recoil by firing two opposed charges simultaneously, with the result that the recoil of each charge, being equal and opposite, is counterbalanced.

B. F. GOODRICH CO.

(*Armory, Southwest Section*)

The principal exhibit by the Goodrich Company consists of one of the first dirigibles put into the United States Naval Service. This is a "Blimp" that was completed in August, 1917, and used for seventeen months in coast patrol work in the vicinity of New York City. The dirigible is 167 feet long, 33 feet in maximum diameter and contains 80,000 cubic feet of gas. This dirigible held the record for continuous flight.

A Curtiss OX motor is used. The car is arranged to carry a crew of three men. In cruising a speed of from 40 to 50 M.P.H. is maintained.

Other exhibits by the Goodrich Company are a model spherical balloon; relief throttle valves perfected by the Goodrich Company and principally the Gammeter valve; shock absorber cords; special parachute attachments; fabrics and cloths for aeronautical use, etc. Another feature of the exhibit will be a short motion picture showing how the balloons are manufactured.

THE GOODYEAR TIRE AND RUBBER COMPANY

(*Garden, Main Floor, Northwest*)

The Goodyear Tire and Rubber Co., of Akron, Ohio, is the most extensive aerostatic exhibit of the show. The outstanding feature of the booth is the dirigible pusher car, completely equipped, of a type which has many sisters in service. A 35,000 cubic foot type "R" military kite balloon is suspended and equipped complete. Attractive models of the twin engine Navy dirigible and a trans-continental passenger dirigible car are on display. These models are complete in every detail, including full set of instruments and controls, lockers and upholstery.

A balloon fabric complete testing laboratory was on exhibition.

Several well-arranged panels of small parts, including rope, cable, cable clamps, thimbles, junctions, manometers and bridal rings gave visitors an idea of the numerous high-grade parts that go into the construction of aerostatic craft. A panel of ropes, with various knots and ties, used by aerial "seamen," show that the art of the sailor of the sea applies to the sailor of the air as well.

A full-sized dirigible car equipped with dual control, indicating devices, including manometers, tachometers, air speed indicators, incidence and bank indicator, clock, driven by an 8-cylinder OX-2 Curtiss motor, of the type used on the FC training dirigible, having a cubic capacity of 85,000 feet, form an interesting part of the Goodyear exhibit. Models of "R" type kite balloon, military free balolons and of the U dirigible are also on display.

The Goodyear Company is represented by Mr. E. R. Preston, manager of the Government sales department, assisted by Mr. W. P. Seiberling, G. M. Kurtz, R. H. Upson and H. T. Kraft, whose names are familiar to all interested in aerostatics.

HARTZELL WALNUT PROPELLER COMPANY

(*Garden, Space* 414-415)

The Hartzell Walnut Propeller Co., manufacturers of "Liberty" propellers, are exhibiting the various types of propellers which they have manufactured. This company's design has been adopted for the Loening plane, and air screws of their manufacture have been purchased in quantity by the Army and Navy for various types of planes, including the 4-bladed propeller used on the HS-1 and H-16 Navy planes.

HENDERSON FORGE AND MACHINE COMPANY

(*Garden, South Balcony*)

The Henderson Forge and Machine Co., of Detroit, are showing the complete line of crankshafts. This company manufactured a large number of Liberty motor crankshafts, and in their exhibit showed them through all the stages of manufacture from the rough casting to the final finished product.

HESS-BRIGHT MFG. CO.

(*Garden, Space* 505)

The Hess-Bright Mfg. Co. are exhibiting their line of high-grade ball bearings on neatly arranged panels. Their product is well known for quality of workmanship and materials, and has been extensively used for aircraft motors.

HART AND HUTCHINSON

(*Garden, Space* 328-329)

This manufacturer is exhibiting lockers for employees, steel stationary cabinets and tool cabinets which are sold extensively to manufacturing concerns.

JAMESTOWN PROPELLER CO.

(*Garden, Space* 112-114)

All sizes of "Falcon" propellers, the product of the Jamestown Propeller Co., of Jamestown, N. Y., of two and four bladed type, with and without metal tips, are on view at the exhibit. This company made a large contribution to the propeller production for the aircraft program during the war.

ARTHUR JOHNSON MFG. CO.

(*Armory, Left Side*)

The Arthur Johnson Company, of New York City, have made a specialty of artistic aeronautic jewelry, and in their display included propeller tie pins, watch fobs, military aviator's wings, brooches and rings. This company is making the official souvenir of the show.

JONES-MOTROLA, INC.

(*Garden, Space* 215-216)

The Jones-Motrola Company, of New York City, are displaying their complete line of air speed indicators, tachometers, altitude indicators, clocks, oil, air pressure and motor thermometers, which were manufactured on Government contract.

LAWRANCE AERO ENGINE CORP.

(*Armory, Space* 626-627)

The Lawrance Model L-1, three-cylinder, Y-type, air-cooled engine, described in detail in the March 3 issue of AERIAL AGE WEEKLY, is attracting favorable attention at the Armory. The motor is rated at 60 horsepower at 1900 revolutions per minute, and has a bore of 4¼ inches and a stroke of 5¼ inches. Its weight is 130 pounds.

LIBERTY STARTERS CORPORATION

(*Garden, Space* 514-515)

The Liberty Starters Corporation of New York City, are exhibiting their electric starter, which has been supplied to the Navy. This starter is electrically operated by a motor built by this company. Its weight is only 29 pounds, yet it delivers 1500 foot pounds and turns over a Liberty motor from 60 to 70 revolutions per minute. The Liberty starter is so designed that a hand crank can be used on the motor if necessary; this being geared to the crankshaft at a ratio of 22 to 1, while the electric motor is geared to a ratio of 240 to 1. For military purposes, a synchronizer for a machine gun was incorporated in the design, but this can be replaced if desired by a generator for supplying power for ignition, lighting or radio.

LUNKENHEIMER CO.

(*Garden, Space* 516)

The Lunkenheimer Company, which has offices in New York, is exhibiting a panel of parts produced in quantity for the aircraft program, consisting of air and oil pressure gauges, pet cocks, gasoline line junctions and piping and other small auxiliary parts.

MACCOMBER WHYTE CO.

(*Garden, Space* 307-308)

The Maccomber Whyte Company, manufacturers of wire rope, has been making streamline wire on government order. This company sent their engineers to England to become familiar with the best practice there and brought back machinery for making cold rolled streamline wire. Their exhibit consists of samples of this product.

Sketches made from life at AERO SHOW by Norman E. Taussig

MARLIN-ROCKWELL CORP.

(*Armory, Space* 618-623)

The Marlin-Rockwell Corporation, manufacturers of the Marlin aircraft gun, is displaying several models of their ordnance, which is familiar to Army aviators. The work of this company has won the encomium of high Government officials and their product has given excellent account of itself against enemy aircraft.

MATTHEWS BROTHERS MANUFACTURING CO.

(*Garden, Space* 510)

The Matthews Brothers Company, of Milwaukee, Wis., manufacturers of "Hamilton" propellers, are presenting an interesting and instructive exhibit of their line of propellers and seaplane hulls. The entire process of propeller manufacture, from the rough plank to the highly finished product, are displaying successively for the benefit of visitors. Finished propellers are shown cut longitudinally and latitudinally, so that the direction and thickness of the laminations and the varying thicknesses from the hub to the end of the propeller could be observed.

A feature of the Matthews exhibit is the hull of the type used on the N-9 Navy elementary training seaplane.

A. J. MEYER

(*Garden, Section* 226-227)

A. J. Meyer has been making turnbuckles for the aircraft industry for several years, and his familiar products are displayed on suitable racks for the benefit of visitors. This company engaged in intensive production during the war in order to fill the contracts which were awarded to them on time.

FRANK J. MOSSBERG

(*Garden, Space* 335-336)

The complete line of Frank J. Mossberg's wrenches and tools are being displayed in their booth at the Garden. These tools are extensively used by the automobile and aircraft industry in the assembly and repair of motors. They need no introduction to the industry, their products having found their way into every motor manufacturing plant.

MOTOR COMPRESSOR CO.

(*Garden, Space* 503)

The Motor Compressor Company, of Newark, N. J., are showing their pneumatic aeroplane motor starter, used by both the Army and Navy, and which is now being supplied to the Post Office Department for mail planes. The starter motor is a four-cylinder double opposed type and is sufficiently powerful to turn over any motor up to 550 horsepower. The pressure tank stores enough air for ten to fifteen starts. This company also manufactures pumping outfits for garages, which are being used at several aeroplane fields to supply pressure for aircraft tires.

NATIONAL ADVISORY COMMITTEE ON AERONAUTICS

(*Garden, Space* 508)

The National Advisory Committee has done extensive testing work of various aircraft accessories and parts, including spark plugs and instruments of all kinds, utilizing the facilities of laboratories throughout the country, including that of the Bureau of Standards of Leland Stanford University. An aerodynamic laboratory has just recently been completed for the use of the Committee at Langley Field. A series of tests on the aerodynamic qualities of hundreds of aerofoils and propellers resulted in the gathering of highly valuable data for the use of designers of aircraft. The exhibit of the Committee includes a great many instruments tested by them as well as charts and graphs explaining its work.

NATIONAL CASH REGISTER CO.

(*Garden, Space* 403-410)

The National Cash Register Company are exhibiting the various types of indicating instruments and wing parts which they made for the Government. This company received a contract for the manufacture of 10,000 tachometers of the famous French "Tel" type shortly after the launching of the American air program. The difficulties in securing quantity production on such a delicate instrument may be realized by the fact that 2,104 tools were made, requiring 55,325 hours of work, were needed to produce the 1,540,000 small parts to build the 10,000 tachometers.

The National Company produced 3,199,000 small screw machine parts for Liberty motors. They made all the metal fittings for the Standard J-1 training plane and made rudders, ailerons and stabilizers for DeHavilan4-4 planes.

In order to secure quantity production on the air speed indicators and tachometers, the engineers of this company evovled a new method of dip brazing to avoid the necessity of using torch dipping.

THE NORMA COMPANY OF AMERICA

(*Garden, Space* 209-210)

The Norma Company of America is displaying a complete line of "Norma" High-Precision Ball Bearings, as used in ignition apparatus, lighting generators, radio-electric apparatus, gyroscopic apparatus, and other high-speed equipment used in connection with the aviation industry.

PACKARD MOTOR CAR CO.

(*Garden, Main Floor, North*)

In designing this line of engines it has been the aim of the Packard Engineering Department to retain all the good features of the Packard and Liberty aircraft engines, and at the same time eliminate features having to do with installation difficulties. The result has been an appreciable saving in weight and an increased reliability in performance.

The Model 1-A-744 Engine. This model has 8 cylinders with a 4¾" bore and 5¼" stroke, set at a 60° angle. Complete with propeller hub, carburetor ignition distributor heads, switch, generator, starting motor and switch, the engine weighs 520 lbs. Starting battery, 40 lbs. additional. Engine water, 25 lbs.; radiator water, 27 lbs.; radiator, 73 lbs. Horsepower, 160 M.P.H, at 1525 R.P.M.

The Model 1-A-1116 is similar to the 8-cylinder type, but is provided with 12 cylinders instead. Weight, 710 lbs. Horsepower, 240 at 1525 R.P.M.

The design of the Model 1-A-2025 engine is similar to the 1-A-1116, but the dimensions are changed as required for 5¾" bore by 6½" stroke. Weight, complete, 1,000 lbs. In spite of the fact that this is one of the largest aircraft engines designed to date, its compact arrangement makes neat streamline installation possible. Horsepower, 440 at 1550 R.P.M.

PERRY-AUSTEN MFG. CO.

(*Armory, Space* 616-617)

The Perry-Austen Mfg. Co. are displaying their dope products, which have been extensively used as wing covering on all types of American aircraft. Of the thousands of gallons of Aus-Per-Ite nitrate and acetate dope which they have supplied to the Army and Navy, not one gallon has been found defective or below standard by Government inspectors.

This company has brought out a new product, a combination of dope and gray varnish which reduces the time required to produce the finished wing. As the varnish is mixed with the dope, cracking and peeling, due to unequal coefficient of expansion of dope and paint, is eliminated.

RADIUM DIAL CO.

(*Garden, Space* 309-310)

The Radium Dial Co. demonstrates the efficiency of their luminous paint by means of a dark room containing several instruments treated with their product. A complete instrument panel of a DH-4 plane, formed a part of their exhibit. A bomb sight, known as Mark I-A, developed by the Government to enable the aviator to drop bombs with the accuracy which marks the direction of artillery fire, and manufactured by the Edison Company, treated with luminous paint, was one of the devices that is attracting considerable attention among the visitors at the show.

JOHN A. ROEBLING CO.

(*Garden, Space* 311-313)

The John A. Roebling Co., of Trenton, N. J., is exhibiting a complete line of aircraft wire, stranded cord, thimbles and ferrules, as well as all types and kinds of wire products and insulated wire as it applies to the aircraft industry. The exhibit is arranged in a series of glass-covered cases, each of which contains complete data relative to the products contained in it.

A novel feature of the exhibit is a coil of wire possessing the highest tensile strength for any wire of its size and weight known in the world. It is ¼ inch in diameter, 6x19 strand steel balloon cable, having a copper conductor in the center for telephonic communication. This wire is furnished to the United States Government for balloon mooring.

SCHNEIDER BROTHERS INSTRUMENT COMPANY

(*Garden, Space* 213-214)

Schneider Brothers Instrument Company, who for the past forty years have been engaged in the manufacture of weather indicating instruments, is displaying their complete line of meteorological instruments both of portable and stationary type, which were used by the Army and Navy in forecasting and recording weather conditions for the use of the air services. Many of these devices were designed by the engineers of the company, whose long experience in design and construction of instruments for the Weather Department was of great assistance in the development of instruments of this type.

This company is exhibiting the famous "Schneider" altimeter, as supplied to the Navy, anemometers for indicating wind velocity, barometers, including the large type used to standardize the meters mounted on planes, and the metereograph, which indicates and records wind velocity, pressure, temperature and humidity.

SIMMS MAGNETO CO.

(*Garden, Space* 344-345)

The Simms Magneto Co., of East Orange, N. J., is showing a complete line of aeroplane and automobile magnetos. Several types of Simms' magnetos have been used for aircraft motors, the L-16 model being suitable for King-Bugatti motors, the L-8 for Hispano-Suiza motors and the CK-8 for the Packard Aviation Motor. This last-named model was used by Ralph de Palma in his record-breaking Packard car, which used the Packard Aviation Motor.

All Simms aviation magnetos are waterproof and the permanent magnets carefully tempered to give the utmost strength of magnetic field with the highest possible retentivity.

SOCIETY OF AUTOMOTIVE ENGINEERS

(*Armory, Space* 635-636)

The standardization work of the Society of Automotive Engineers as an important contribution to war production is graphically displayed by a series of glass-covered panels showing the standards established by this society for heat-treated steels, adjustable yoke rod ends, plane yoke rod ends, eye rod ends, rods and pins, bolts and nuts and threads. These standards have been published from time to time in AERIAL AGE WEEKLY and are the guide of the aeronautic engineer.

A. G. SPALDING BROS.

(*Armory, Space* 641-642)

The A. G. Spalding Company, of New York, Chicago, San Francisco and Los Angeles, have a complete line of aviators' and yachtsmen's clothing on view at the Exposition, including several types of helmets, goggles, wool hoods, masks, leather coats and trousers, leather vests, gloves, mittens and gauntlets, mackintosh waders for naval aviators and fleece-lined boots and shoes. The Spalding Company has developed a non-sinkable coat, guaranteed to keep a man afloat on the water fully sixty hours. Their complete line fills every need.

LAWRENCE SPERRY AIRCRAFT CO.

(*Armory, Southeast*)

A new type of indicating instrument of great value to the air pilot is being exhibited by the Lawrence Sperry Aircraft Company, of Farmingdale, Long Island. This device is a turning indicator, which instantly responds to any change in lateral direction of flight, yet is unaffected by side gusts and banking, unless accompanied by turning motion. This device is demonstrated by a model plane, fitted with the new instrument, which showed instant deflections when its lateral direction was changed.

The familiar Sperry banking indicator and the Sperry compasses are again in evidence.

The W. B. motor is making its first appearance at the show, and it will be described in detail in a future issue. It is a light-weight four-cylinder, V type, air-cooled, 129¾-pound motor, developing 38 horsepower. Reliability, simplicity and economy of operation are its chief characteristics at 1800 revolutions per minute. An engine of this type is installed in the Dayton-Wright "Messenger" aeroplane. The Sperry Company has also arranged to have a running test of the engines at a nearby garage where ten-hour endurance runs will be made. A detailed description of this motor will appear in a future issue of AERIAL AGE WEEKLY.

Sperry is also exhibiting a special parachute and launching device, and a constant speed air fan developed for the War Department to drive radio generators.

SPLITDORF ELECTRICAL INSTRUMENT COMPANY

(*Garden, Space* 521)

The Splitdorf Electrical Instrument Company is displaying their complete line of magnetos and ignition parts, including the two magneto unit for use on Liberty motors. This company manufactures complete ignition outfits for all sizes of aircraft and automobile motors, as well as distributors and electrical measuring instruments.

STANDARD PARTS CO.

(*Armory, Space* 610-611)

The tremendous achievements of this company in the production of aeronautic parts of all kinds in their various factories through the Middle West has earned for them a place in the parts manufacturing industry second to none. The company is represented at the exposition by various members of the sales and executive forces.

STERLING ENGINE CO.

(*Garden, Exhibition Hall*)

The Sterling Engine Co., of Buffalo, N. Y., are manufacturers of marine motors ranging from 10 to 300 horsepower with from 2 to 8 cylinders. This firm is exhibiting a comprehensive line of marine motors, including various types made for the American, French and British Government for use on seaplane tenders. The Sterling Company completed a contract for Sunbeam motors for the United States Government.

STEWART HARTSHORN CO.

(*Garden, Space* 317-318)

The Stewart-Hartshorn Co., manufacturers of streamline wire, are exhibiting their products on panels, showing the nine stock sizes which they have supplied in quantity. The Hartshorn strap end, which is their exclusive product, has been

submitted to most rigid tests and has shown a breaking strength in excess of 200,000 pounds per square inch for the wire for which it is designed. The wire itself has a breaking strength of 165,000 to 175,000 pounds, which shows that the strap end will hold even if the wire is strained to the breaking point. DH-4 planes manufactured by the Standard, Dayton-Wright and Fisher Body Corporation and the SE-5 seaplane manufactured by the Curtiss Company were exclusively equipped with Hartshorn streamline wire. This company also completed a contract for Liberty motor valve springs.

STONE PROPELLER CO.

(*Garden, Space* 138-139)

The Stone Propeller Co., of Dayton, Ohio, one of the pioneers of the propeller industry, are manufacturing the propeller used on La Pere fighters and have completed a large contract for propellers for use on the DH-4 plane and for planes using Hispano-Suiza, Rolls-Royce, Curtiss, Hall-Scott, Gnome and LeRhone motors. This company is displaying their complete line of propellers for the industry, ranging from a small 6 foot 6 inch size for use on Ford motored aeroplanes to some of the largest sizes in use.

STROMBERG MOTOR DEVICES CO.

(*Garden, Space* 504)

The Stromberg Motor Devices Company exhibit includes a series of models of carburetors suitable for aviation engines of all sizes and powers. The NAV-6 model is used on the 300-horsepower Hispano-Suiza motor; the NAD-6 on the 180-horsepower Hispano-Suiza, and the NAD-6 on the Thomas Morse 8-cylinder. This carburetor was used on the Loening plane in establishing the 3-passenger speed record and on the plane which recently established the American altitude record of 29,500 feet.

TIPS AERO ENGINE CO.

(*Garden, Space* 125-126)

The Tips Aero Engine Company is exhibiting for the first time their 18-cylinder, 480-horsepower rotary motor, which has a weight of only 850 pounds. This motor is of radical design of the utmost simplicity, using rotary valves, permitting of exceptional cooling and lubrication. This motor has just been completed by the engineers of this company and possesses many original and interesting features of design.

TITEFLEX METAL HOSE CORPORATION

(*Armory, Space* 624-625)

This company has brought out a special unpacked, absolutely tight all metal tubing that possesses inherent flexibility instead of depending on the movement and slipping of a joint to obtain bending. This material overcomes the limitations of the flexible metal tubing that has heretofore been available, in that absolute tightness is obtained, yet possesses a greater degree of flexibility without the lessening of the degree of either at the expense of the other. It has been impossible heretofore to obtain a material that would successfully handle very high pressures, and one that would give a satisfactory degree of durability, and although this new tubing is slightly more in first cost, it proves itself to be most economical by giving longer life in service.

The manufacturer's whole facilities were given over to the Government during the war to supply this product to the various departments, and in a number of instances it was found to be the only tubing that could satisfactorily meet the drastic requirements in the special installations that were made.

The Bureau of Aircraft Production used an assembly of this tubing with fittings as an all-metal gasoline feed line from the fuel supply tank to the carburetor on various planes, and the Bureau of Steam Engineering of the U. S. Navy equipped several types of seaplanes and dirigibles with this tubing for conveying gasoline, oil and air. It is a noteworthy fact that the Caproni in the service of the Italian Government were considering the use of this material in connection with their plane work at the time of the closing of the war.

Additional uses by the United States Government were as gasoline, oil, water and air lines on standardized trucks, caterpillar type of tractors, battle tanks, heavy mobile gun mounts, etc. The tubing lends itself to many interesting uses, an instance being that of the Eastman Kodak Co., which is employing it as a protecting housing around a revolving shaft on aeroplane cameras.

This company is identified with Westinghouse interests, Mr. H. H. Westinghouse being chairman of the Board of Directors, and its official personnel is composed of Mr. C. W. Fletcher, president and general manager; H. R. Smith, secretary and treasurer; W. H. Fulton, chief engineer, and C. E. Mackay, director of sales. The general office and works of the company are at Badger Avenue and Runyon Street, Newark, N. J., where the plant facilities of the organization are modern and of large capacity and with space in reserve for expansion.

TORRINGTON COMPANY

(*Garden, Space* 104-107)

The Standard Plant of the Torrington Co., of Torrington, Conn., was devoted to the manufacture of streamline wires, tie rods, clamps, lock nuts, washers, spokes and nipples for aeroplane wheels for the aircraft program. A complete exhibit of all sizes and types of such parts mounted on display racks forms the principal part of this company's exhibit.

The Langley, the first American-built Handley Page, is equipped with Torrington streamline wire. A full set of DH-4 wires and fittings, as manufactured by this company, was mounted on racks and forms an interesting part of the exhibit.

TRIPLEX SAFETY GLASS CORPORATION

(*Armory, Space* 637-638)

Safety goggles of all kinds for aviators are in evidence at the Triplex booth. These goggles have earned an excellent reputation among military aviators, for they have contributed substantially to the safety of flying. Although a blow can shatter them, the glass does not splinter, thus eliminating all danger to the aviator's eyes.

U. S. BALL BEARING CO.

(*Garden, Space* 120-122)

This company is displaying its complete line of ball-bearing products, large quantities of which have entered into the construction of motors for the military aircraft program.

VALENTINE & CO.

(*Garden, North Balcony*)

This company is exhibiting their full line of waterproof varnishes, which are extensively used on seaplanes and propellers. A feature of their exhibit is a propeller which was kept in motion in a glass tank of water, without there being any visible deleterious effect on the propeller varnish.

VAN SICKLEN CO.

(*Garden, Space* 502)

The Van Sicklen Company, manufacturers of tachometers and oxygen equipment, has an interesting exhibit of their various products. The Prouty oxygen system, developed by this firm for supplying the aviator with the necessary oxygen at high altitudes, is considered superior to the devices used by foreign governments. Not only is the oxygen supply regulated according to the altitude of the plane, but compensation is made for decreased tank pressure due to dropping of temperature. The supply tank holds 800 litres of oxygen at a pressure of 150 pounds. The instrument is equipped with an accurate pressure indicator, and a simple regulator for increasing the supply from one to two men, as needed.

The altimeter designed and built by this company has a specially designed diaphragm which eliminates the use of the chain drive for the indicating needle, this obviating the chief cause of inaccuracy for this type of instrument. Furthermore, the diaphragm expands uniformly according to the altitude, thus making an even scale possible without compensating gears.

WELLINGTON, SEARS AND CO.

(*Armory, Space* 628-630)

The Wellington, Sears & Co., of Centerville, R. I., which manufactured every type of aero-

THE NEWS OF THE WEEK

Aeroplane for Oversea Flight Now Being Rushed at Navy's Factory

According to press dispatches, a type of naval aeroplane, which in point of size, power and carrying capacity greatly exceeds the N C-1, is now under construction at the Navy's League Island aircraft factory in Philadelphia, it became known recently when an aircraft designer, who has been at the factory, described its features in detail.

The designer, who would not consent to have his name made public, said that work on the plane was going on night and day in order to have it ready as soon as possible for the contemplated trans-Atlantic flight. Officials of the Navy's Air Service, he said, had great faith in the new flying boat, and believed it would accomplish a trip to Europe with little or no difficulty.

The design of the new super-aeroplane, which is known as Model T, is similar to the Navy's F-5, now being shown at the Aeronautical Exposition. It has an upper wing span of 250 feet, which is 124 feet more than the N C-1. The lower wing is 25 feet less. The length of the craft over all is 80 feet. The wings are 12 feet broad and 14 feet apart.

The motive power for the new naval aeroplane will be supplied by five Liberty motors of 400 horsepower each. Three will be tractors and two pushers.

Seventy-five passengers will be able to ride comfortably in the Model T, according to press dispatches, making ample allowance for tanks carrying sufficient gasoline and oil for a flight of 2,000 miles. The N C-1 has carried fifty-one passengers on one of its trips. If the new Model T lives up to the hopes of its builders, it will establish a new passenger-carrying record.

Construction on the machine has progressed so rapidly that its completion is expected in the very near future, according to the aircraft designer who told of its details. He was unable to express himself more definitely as to the date of its completion, he said, because of the many unforeseen difficulties which arise in building aeroplanes of a new type.

Lieutenant Flachaire Returns to United States

New York, N. Y.—Lieutenant Georges Flachaire, who spent several months in the United States last year and has many friends and admirers in this country, arrived in New York recently on the S. S. *Touraine*. Lieutenant Flachaire has been decorated with nearly every military medal that can be conferred on a French flying officer.

Congress Aids Ground Training in Colleges

Washington, D. C.—The joint resolution which the Senate recently passed was modified to insure that the loaning of air service equipment to colleges be confined to ground training. It authorizes the Secretary of War to loan aircraft engines and equipment to encourage the development of the science of flying, for the loans are to be made to "such educational institutions as provide advanced mechanical and technical instructions." The first application for the loan of such equipment has been made by the College of the City of New York.

Radio Telephones at Aero Show

New York, N. Y.—The Division of Military Aeronautics has authorized Lieutenant J. E. Adams, of Hazelhurst Field, Mineola, L. I., to conduct formation flights over Madison Square Garden during the Aeronautical Exposition. The flights are made daily between noon and two o'clock and directed by radio telephones at the Exposition. Telephone receivers for visitors are available, making it possible to hear the orders transmitted, in the same way as the aviator in the plane above hears them.

S. A. E. Aeronautic Meeting

New York, N. Y.—The Society of Automotive Engineers, held on March 7, during the Aeronautic Exposition, a meeting at which many important engineering questions involved in the commercial use of aircraft will be presented and discussed.

An afternoon session began at four o'clock at the headquarters of the S. A. E., 29 West 39th Street, this being followed by a supper there, at which an informal conference of the automotive engineers and their guests afforded an opportunity to take up in an intimate way just what is possible, new or in sight in the commercial as well as sporting use of aircraft.

At the afternoon session C. H. Day had as his subject "The Commercial Future of Aeroplanes from the Engineer's Standpoint." Archibald Black, of the United States Navy, summarized a comprehensive paper he had prepared for the S. A. E. on Aircraft Radiators.

At the evening session representatives of the Army and of the Navy, as well as of the industry, who are engineering authorities on aeronautics, addressed the members.

March 7 was designated officially as S. A. E. day by the management of the Aeronautical Exposition.

Civilian Flying Licenses to be Required

In the February 24 issue of AERIAL AGE we printed the Aero Club of America's recommendations to provide for the registration of aircraft and aviators by the Department of Commerce.

It is announced that President Wilson, in submitting to the House the recommendations of the National Advisory Committee for Aeronautics for legislation placing the licensing and regulation of aerial navigation in charge of the Department of Commerce, declared that he "fully approved the suggested legislation." Secretaries Baker, Daniels and Redfield also indorsed the proposal.

The legislation would give the Department of Commerce authority to issue licenses for civilian operation of aircraft and provides an appropriation of $25,000 for the necessary expenses. A letter from C. D. Walcott, Chairman of the Executive Committee, said the legisaltion should be passed at the present session. Mr. Walcott, pointing out the absence of any Federal authority for establishing rules and regulations governing civilian operation, said if the War Department sold its surplus machines many amateurs would attempt flying, which would result in many accidents. Operation of "unlicensed and irresponsible aircraft," he added, would cause probably complications through smuggling from Mexico and Canada.

Discharge Emblem Selected

Washington, D. C.—The War Department authorizes the following statement:

The "honorable discharge" emblem to be issued by the War Department will be a bronze lapel button somewhat similar to the G. A. R. button of like significance. It is the intention of the Government to distribute the button free of charge to all entitled to it. The buttons will be manufactured only by concerns chosen by the Government, which will furnish the dies for their manufacture and purchase the buttons, thus obviating any possible variance from the approved pattern in design, color or material.

Of appropriate and artistic design, the button is the result of a competition among American artists and sculptors, conducted by the Commission of Fine Arts of which Charles Moore is chairman, and the following are members: Herbert Adams, J. Alden Weir, Charles A. Platt, William Mitchell Kendall, John Russell Pope, James L. Greeneaf and Col. C. S. Ridley, secretary. Fifteen designs were submitted by the commission for final selection by the Chief of Staff.

Secretary Daniels Commends Naval Airmen

Secretary Daniels has commended the men of the office of the Inspector of Engineering Material, Brooklyn Aeronautic District; also the men of the Navy Aviation Mechanics School for carpenter's mates, Keyport, N. J., for the splendid manner in which they conducted themselves while on guard duty during the fire at Morgan, N. J., on the night of October 4, 1918.

Distribution of Aircraft Personnel in U. S. and Overseas

The Statistics Branch, General Staff, War Department, issues the following table, showing the distribution of the military aeronautics personnel in the United States and overseas at various dates:

	In United States	Overseas	Per cent. In United States	Overseas
Nov. 11	79,321	78,786	50	50
Nov. 18	80,689	78,973	51	49
Nov. 25	84,785	78,361	52	48
Dec. 2	84,844	78,061	52	48
Dec. 9	89,661	70,040	56	44
Dec. 21	81,607	61,345	57	43
Dec. 26	77,140	59,917	56	44
Jan. 6	67,833	59,584	53	47
Jan. 16	51,821	58,854	47	53
Jan. 23	46,467	58,133	44	56
Jan. 30	41,314	57,527	42	58
Feb. 6	37,537	56,299	40	60

Army Aviators Fly Over Grand Canyon 1,400 Feet Up

Kingman, Arizona.—What was said here to-day to have been the first aeroplane flight over the Grand Canyon of the Colorado was made by Lieuts. R. O. Searles and E. D. Jones in a De Haviland bombing plane. They flew from Kingman to the canyon and return after following its course for many miles. The flight was made at an altitude of about 14,000 feet and lasted two hours.

Only Two U. S. Units Cited as a Whole

Washington, February 25.—Only two units of the United States Army, Sanitary Section No. 646 and the 103 Aero Squadron, have been authorized to wear the French shoulder cord, known as the fourragere, indicating that the unit as a whole has been cited for gallantry in action. This was disclosed in a circular made public by the War Department relative to uniform and decorations.

The Pilot's and the Observer's cockpits on the D. H. 9 machine with which, on January 2, an altitude record of 30,500 ft. was made at Martlesham by Capt. Lang, R. A. F., as pilot, and Lieut. Blowes as observer, both of whom are inset. The machine was equipped with a Napier "Lion" engine. The two oxygen tubes, which supplied the oxygen, are shown back of the windshield of the rear seat

Will Advise Brazilian Navy

Washington.—Assignment of Lieutenant-Commander Wadleigh Capehart, of the office of naval operations, to duty as adviser to the Brazilian Government on naval aviation matters, was announced in navy orders.

Authorization for Travel Expenses Made by War Department

Washington, D. C.—A paragraph of General Order 22 makes possible reimbursement of officers, men and civilian employees for travel expenses incurred in line of duty:

3. Section IV, General Orders, No. 27, War Department, 1918, as amended by Section III, General Orders, No. 81, War Department, 1918, is rescinded and the following substituted therefor:

"Actual and necessary expenses, not exceeding $5 per day, may be paid from the Signal Corps appropriation of July 24, 1917, or from the Air Service appropriation of July 9, 1918, to officers, enlisted men, and civilian employees of the Army, and authorized agents when sent on special duty for aviation purposes at home or abroad under specific instructions from the Secretary of War."

Vouchers submitted for payment under the provisions of this order will be accompanied by an itemized statement of expenses.

College of City of New York Starts More Aeroplane Courses

New York, N. Y.—The College of the City of New York is still enrolling students for its four courses on aeronautics, outlined below. The equipment of the school is valued at $85,000, and is on exhibition during the period of the Aeronautical Exposition at Madison Square Garden at Compton Hall every evening, except Sundays.

The instruction is designed to prepare men for the flying school, mechanical jobs with aircraft and motor companies, for positions as draftsmen, designers and aeronautical engineers. They are preparatory courses for the regular courses that will be established for a degree.

The schedule is as follows:

Aeroplane Mechanics: Lectures and laboratory work on general principles of construction and operation of an aeroplane. Course—eight weeks—two nights per week. Starts March 14. Fee $10. Laboratory, Wednesday, 7:30 to 10:15 P. M. Lecture, Friday, 7:30 to 10:15 P. M.

Advanced Aeroplane Mechanics: Lectures and laboratory work on general principles of construction and operation of aeronautical motors, both American and foreign design. Course—eight weeks—two nights per week. Starts March 14. Fee $10. Lecture, Wednesday 7:30 to 10:15 P. M. Laboratory, Friday 7:30 to 10:15 P. M.

Aeroplane Drafting: Practical work in detail and assembly drawings of airplanes and parts. Emphasis will be given to the development of practical production drawings following the systems used in all modern production plants. Course—eight weeks—two nights per week. Starts March 15. Fee $10. Drawing Room, Monday and Saturday 7:30 to 10:15 P. M.

Aeroplane Design: This course covers the theory and design of different types of airplanes. The complete engineering calculations of two machines are worked out in the classroom and in addition, each student works out the design of an original machine. There are no requisites for any of these courses but the instructors are glad to advise prospective students relative to their program. Course—eight weeks—two nights per week. Starts March 18. Fee $10. Lectures, Tuesday and Thursday 7:30 to 10:15 P. M.

Mr. E. C. McHugh, formerly in charge of an operating department of the Dayton-Wright Aeroplane Company, has accepted the position of works manager of the Stueben Truck Co., Cincinnati, Ohio.

Sir Charles Allom, one of the principal members of the British firm, Gosport Aircraft Co., has been visiting the United States for some time and has opened officers at 19 East 52nd St., New York.

Official Regulations for Transatlantic Flight

The $50,000 *Daily Mail* Prize for the first trans-Atlantic flight made within 72 consecutive hours is being offered under the following conditions formulated by the Royal Aero Club:

Qualification of Competitors.—The competition is open to persons of any nationality not of enemy origin, holding an Aviator's Certificate issued by the International Aeronautical Federation and duly entered on the Competitors' Register of the Royal Aero Club.

No aeroplane of enemy origin or manufacture may be used.

Entries.—The Entry Form, which must be accompanied by the Entrance Fee of £100, must be sent to the Secretary of the Royal Aero Club, 3, Clifford Street, London, W. 1, at least 14 days before the entrant makes his first attempt.

No part of the Entrance Fee is to be received by the *Daily Mail*. All amounts received will be applied towards payment of the expenses of the Royal Aero Club in conducting the competition. Any balance not so expended will be refunded to the competitor.

Starting Place.—Competitors must advise the Royal Aero Club of the starting place selected, and should indicate as nearly as possible the proposed landing place.

All starts must be made under the supervision of an Official or Officials appointed by the Royal Aero Club.

Identification of Aircraft.—Only one aircraft may be used for each attempt. It may be repaired en route. It will be so marked before starting that it can be identified on reaching the other side.

Stoppages.—Any intermediate stoppages may only be made on the water.

Towing—Towing is not prohibited.

Start and Finish.—The start may be made from land or water, but in the latter case the competitor must cross the coast line in flight. The time will be taken from the moment of leaving the land or crossing the coast line.

The finish may be made on land or water. The time will be taken at the moment of crossing the coast line in flight or touching land.

If the pilot has at any time to leave the aircraft and board a ship, he must resume his flight from approximately the same point at which he went on board.

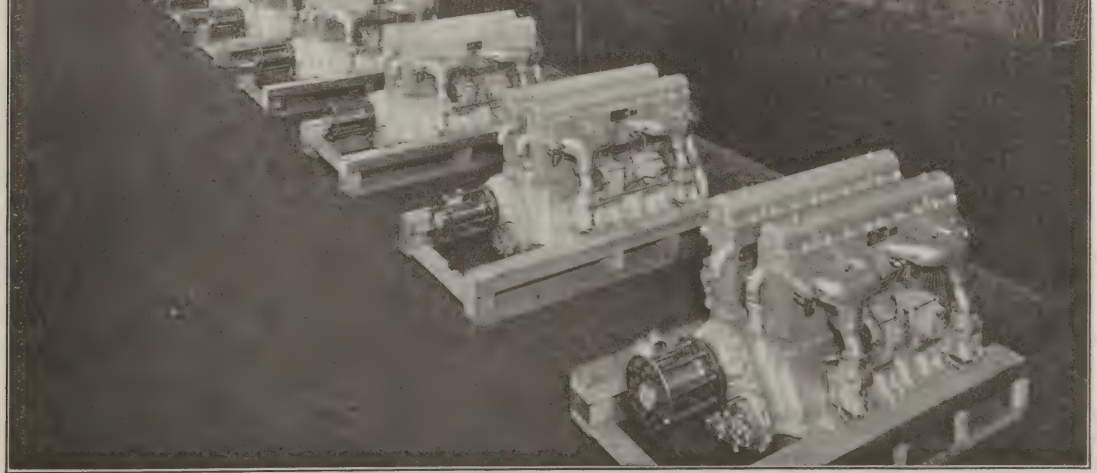
General

1. A competitor, by entering, thereby agrees that he is bound by the Regulations herein contained or to be hereafter issued in connection with this competition.

2. The interpretation of these regulations or of any to be hereafter issued shall rest entirely with the Royal Aero Club.

3. The competitor shall be solely responsible to the officials for the due observance of these regulations, and shall be the person with whom the officials will deal in respect thereof, or of any other question arising out of this competition.

4. A competitor, by entering, waives any right of action against the Royal Aero Club or the proprietors of the *Daily Mail* for any damages sustained by him in consequence of any act or omission on the part of the officials of the Royal Aero Club or the Proprietors of the *Daily Mail* or their representatives or servants or any fellow competitor.



5. The aircraft shall at all times be at the risk in all respects of the competitor, who shall be deemed by entry to agree to waive all claims for injury either to himself, or his passenger, or his aircraft, or his employees or workmen, and to assume all liability for damage to third parties or their property, and to indemnify the Royal Aero Club and the proprietors of the *Daily Mail* in respect thereof.

6. The Committee of the Royal Aero Club reserves to itself the right, with the consent of the Proprietors of the Daily Mail, to add to, amend or omit any of these rules should it think fit.

1 February, 1919.

Offices: The Royal Aero Club, 3, Clifford St., London, W, 1, H. E. Perrin, secretary.

The Aero Club of America will receive the entries in the United States and will carry out the Royal Aero Club's rules and regulations.

A line-up of King-Bugatti aviation motors at the Duesenberg Motor Corporation, Elizabeth, N. J.

The AIRCRAFT TRADE REVIEW

Conference On Disposal of Surplus Plywood and Veneer

Conferences were held February 13 and 19, 1919, in the Council of National Defense Building, Washington, D. C., and were attended by the following representatives of the Government and a committee representing the plywoods and veneers industry:

War Department

Maj. W. M. Crunden, Office of Director of Sales; Maj. D. J. Beem, Ordnance Department; Capt. J. L. Synder, Bureau of Aircraft Production; Lieut. William J. Walsh, Bureau of Aircraft Production; W. P. Gleason, Office of Director of Sales; Fred S. Morse, Surplus Property Division; Edw. D. McConnell, Bureau of Aircraft Production; Frank R. Ing, Bureau of Aircraft Production; Lieut. C. P. Cronk, Bureau of Aircraft Production; W. E. Farnan, Bufreau of Aircraft Production.

War Industries Board

Richard L. Humphrey, director of building materials, Building Materials Division; M. A. Styles, Building Materials Division.

Plywoods and Veneers Industries

O. C. Lemke, Underwood Veneer Co., Wausau, Wis.; P. M. White, Algoma Panel Co., Algoma, Wis.; C. Fred Calhoun, Frosts' Veneer Seating Co., Sheboygan, Wis.; C. B. Allen, Allen Eaton Panel Co., Memphis Tenn.; F. W. Eggers, Eggers Veneer Seating Co., Two Rivers, Wis.; W. H. Rodis, Rodis Lumber & Veneer Co., Marshfield, Wis.

The chairman of the conferences, Richard L. Humphrey, stated the purpose of the meeting was to consider a method of procedure for the disposal of Government surplus stocks of plywood and veneers that would be for the best interests of the Government and at the same time meet with the approval of the industry.

As a result of these conferences a method of procedure was unanimously agreed to by the representatives of the Government and of the industry by which these stocks will be disposed of by the Government in cooperation with the industry.

The plan of procedure agreed to covers only the surplus stocks that are not absorbed through redistribution among the several bureaus of Government use.

The representatives of the industry expressed their gratification at the outcome of the conferences and the belief that the method of procedure which had been agreed to would remove the uncertainty and menace which these stocks have exercised over the veneer and plywood market.

Christian Girl Back at His Desk

Cleveland.—Christian Girl, president of the Standard Parts Co., who has been South recuperating from a slight operation this fall, is again in good health, and will resume his busines duties in April.

Personal Pars

Lieut. Fred. M. Young, who has recently returned from overseas duty in the air service, has become associated with the Perfex Radiator Co., Racine, as sales engineer.

Dedell Heads Firestone Advertising

Akron.—J. R. Dedell, until recently connected with the Corday & Gross Advertising Co., Cleveland, has been appointed advertising manager of the Firestone Tire & Rubber Co., Akron.

The Martin Cruising Bomber

The Martin Cruising Bomber is equipped with two engines located in the fuselage and driving two tractor propellers by means of bevel gear transmission. Since either engine will drive both propellers, the failure of one of the engines does not impair the efficiency of the plane.

Either two Sunbeam 300 H.P. engines drive the plane at 74 M.P.H., or two Liberty 400 H.P. engines will drive plane at 81 M.P.H.; in either case with a two ton useful load.

Fully loaded the machine can make a speed of 110 miles an hour. The useful load is three tons not including one ton of fuel and oil.

The K-bar cellule truss is used, which eliminates half of the cellule structural resistance due to wires transverse to the line of flight.

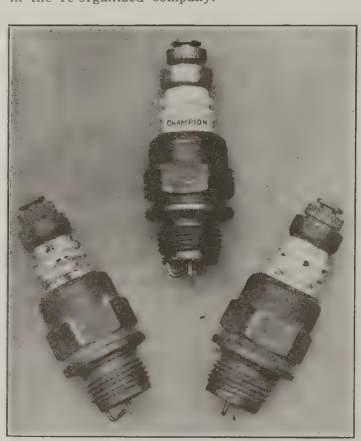
The machine is also provided with the Martin retractable landing chassis, which has been found to be strong, light and reliable. It eliminates 14 per cent of the structural resistance of the Bomber.

Mr. Martin claims that safety and dependability are increased because of independent transmission support, for the propeller breakage will not endanger cellule truss, and because cellule strusses are low and are more accurately calculable.

As the engines are enclosed, resistance is no greater than where a single engine is used. Such placing makes the engines accessible for minor repairs and adjustments.

H. H. Newsom Back With Standard Parts

Mr. H. H. Newsom is back with the Standard Parts Co. as manager of the Standard Welding Plant. In the spring of 1918, the Director of Aircraft Production requested the services of Mr. Newsom in connection with engineering and production work on radiators, Mr. Newsom's experience as production manager and director of purchases for the Standard Parts Co., then one of the few manufacturing concerns having extensive experience in the construction of radiators for military aeroplanes, particularly fitting him for the duties of his position. The department with which he was identified ten folded the output of radiator manufacturing concerns then in production.



Laureati's Aeroplane at City College Exhibit

The aeroplane in which Capt. Giulio Laureati, the Italian aviator, made the historic London-Turin flight of 656 miles in six and a half hours, has been placed on exhibit in the College of the City of New York. Capt. Laureati crossed the Alps at a height of 12,000 feet.

The machine was obtained through the Italian Aeronautical Society. The addition swells the aeronautical collection of the college, and the trustees have decided to push to completion the concrete structure begun on the college grounds under Government auspices, which was to have housed the Students' Army Training Corps. The college paid the United States $3,000 for the semi-finished building.

American Bosch Stock All Sold

February 8th—Hornblower & Weeks announce that the underwriting of the notes of the American Bosch Magneto Corporation and sale of the common stock has been closed. The rapid financing of this company is an indication of the optimism and confidence which investors have in the re-organized company.

Champion Plugs Withstand Heat Test

Champion spark plugs, manufactured by the Champion Spark Plug Co., of Toledo, Ohio, were recently made the subject of a rather severe heat test, and, as shown in the accompanying cut, withstood the test remarkably well. A training plane "crashed" and the wreckage caught fire. The intense heat destroyed not only all combustible parts, but such metal parts as the crank case and bearings. After the fire died down, the spark plugs were removed, and found in good condition.

Hooven Radiator a Combination of Tubular and Honeycomb

The Hooven radiator, manufactured by the Hooven Radiator Company of Chicago, presents several novel features. It is a combination of the tubular and honeycomb types, the tubes being pressed into sheet metal running vertically, giving larger water passages and allowing a free circulation of water, thus reducing chance of clogging. By slightly building up the ends of the sheets to a width of ⅛ inch on each side with a different angle that is pressed into the water section of the core and corrugating the metal horizontally the honeycomb feature is obtained. This allows a space for a sheet of water 1/16 inch thick circulating between tubes through a staggard channel.

The relation between the cross sectional area of the water passages and its corresponding air passage cross sectional area was determined from a great number of experiments varying the water flow against the average air velocities and an empirical equation was derived.

The rigidity and durability of the radiator is greatly increased because the tubes are pressed vertically and corrugated horizontally, this making re-enforcement in both directions. The top and bottom sections of the radiator core are not merely bent over and soldered, but both lock-seamed and soldered.

Christensen Starter Survives Severe Official Tests

The Christensen starter, which has been successfully applied to Liberty, Hispano-Suiza, Duesenberg and other aircraft motors, was subjected to most severe tests before being approved for use on Government planes. The Christensen starter is a compressed air starter, which not only sets the motor in motion by means of an injection of air at high pressure into the cylinders of the motor, but insures easy and rapid starting, because the compressed air supplied to the cylinder is richly impregnated with gasoline vapor.

In a Signal Corps test of a No. 12 type starter on a cold and stiff Liberty 12 motor to determine the number of starts that could be obtained without recharge of the pressure tank, 12 starts were made in an average time of two seconds each, 19 pounds of pressure being taken from the tank for each start. The time required to recharge the tank to full pressure was 2 minutes and 45 seconds.

A test to ascertain how long the motor would run on the starter mixture with the main carhureter shut off gave the following results: Total running time, 34.2 seconds; tachometer reading, 350 R. P. M.; total number of revolutions obtained during test period, 118; motor fired evenly and regularly during test.

Captain Jean Richard of the French Commission and Captain Boer of the British Mission conducted tests to find out how many starts could be obtained from one charge of the pressure tank, with the following results: 13 starts in an average time of 1.77 seconds each were made with a cold motor having cold city water flowing through the cooling system.

At a test on a seaplane with a Liberty 12 motor at Great Lakes Naval Training Station, 20 starts were made in an average time of 1.29 seconds, some of these being made in less than 1 second.

On a Hispano-Suiza 8-cylinder motor 24 starts were obtained from a tank charged to 240 pounds pressure. When the test was completed, 150 pounds of pressure still remained, this being sufficient to obtain several more starts. On a plane in flight 1¼ seconds was sufficient to restart a dead motor.

Aluminum Co. Bonds On Sale

The Aluminum Company of America has sold $12,000,000 serial 6 per cent. gold notes to the Guaranty Trust Company of New York and the Union Trust Company and the Mellon National Bank of Pittsburgh. The notes, now on sale, will be dated March 1 and will mature in blocks of $4,000,000 each on March 1, 1921, to 1923, inclusive. Announcement was made recently that the Aluminum Company's net earnings in each of the last four years, after providing for taxes and depreciation, had been more than $8,000,000.

An Aero Mail Questionnaire

Otto Praeger, Second Assistant Postmaster General in charge of Aero Mail, has sent out a questionnaire to the pilots in the service with a view to getting consensus of opinion on the desirable type of aeroplane for the mail service. So that this discussion may be of the utmost value to the Post Office Department AERIAL AGE is presenting herewith the questionnaire with the request to our readers that they send their suggestions to Otto Praeger, Second Assistant Postmaster General, Washington, D. C.

QUESTIONNAIRE

Requirements for Ideal Mail Ship

It is requested that you fill out the following question forms, the purpose of which is to aid the Post Office Department in the development of a commercial type ship, suitable for schedule flying. You are asked to place your answers on another sheet with the proper number and letter designations.

1. *General Specifications.*
   a. How many motors?
   b. Mailing load in pounds at 17½ pounds per cubic foot?
   c. Should a pilot-mechanic be carried?
   d. Do you think wings should hinge on large ships for storage purposes, and how?
   e. At what altitude should ship be balanced?
2. *Performance* (normal load)
   a. What should cruising speed be, and at what altitude measured?
   b. Minimum buoyancy speed?
   c. Cruising radius?
   d. Have you an idea for slow landing device, either inherent or mechanical; if so, what?
   e. What should climb of 6,000 ft. be, and what service ceiling?
   f. What percentage of normal maximum power should keep a ship at an even altitude?

Ship by Units

1. *Motors*
   a. Where should motor or motors be located.
   b. Should each be independent?
   c. Should they be accessible during flight, and how?
   d. Do you recommend motor starters? What type?
   e. Should radiators have complete shutters?
2. *Fuselage.*
   a. How would you distribute landing gear stresses?
   b. How and where would you place loads?
   c. Have you any suggestions for carrying mails?
   d. Would you alter present type of tail skid? How?
   e. Should skid be steerable from rudder bar.
3. *Wings.*
   a. State ideas for wing construction.
   b. What factor of safety?
   c. Have you any changes to suggest in wing skids?
   d. What wing loading do you think advisable?
4. *Landing Gear.*
   a. Give desirable factor of safety?
   b. Where place?
   c. Do you think three strut landing gear visable?
5. *Controls and Control Surfaces.*
   a. "Dep" or stick?
   b. Should controls be accessible in flight?
   c. Should all control surfaces be balanced?
   d. Do you think stabilizer should be hinged?
6. *Gas and Oil.*
   a. Should each motor have independent gas and oil?
   b. What feed system should be used?
   c. Do you recommend accessibility for all valves and leads during flight? How placed?
   d. How should gas and oil tanks be anchored and where placed?
   e. How would you provide leads against vibration?
7. *Safety and Comfort of Crew.*
   a. Should pilot and mechanic, if any, be placed before or behind the main load?
   b. Should cock-pit be enclosed or open?
   c. How should cock-pit be heated for winter flying?
   d. Should there be passageway through fuselage to vital parts?
   e. State in detal your ideas for location of controls, instruments, seats and the amount of room available in cock-pit.
   f. Can you suggest an adequate fire extinguisher system?

French Aerial Mail Service Officially Started

Paris—On March 1st the French aerial mail service between Paris and Bordeaux, Marseilles, Toulouse, Brest and St. Nazaire, under the supervision of the director of civilian aeronautics, was officially inaugurated.

Post Office Receives Bids for DH-4 Changes

Abstract for bids for changing and modifying 12 De Haviland 4 aeroplanes and as many more up to 60, in lots of 12, as the Postmaster General may direct. Opening of bids took place February 26, 1919.

Bidder	Price, each	Total
Curtiss Engineering Corporation, Garden City, L. I., New York.....	$1,975.00	$23,700.00
Aircraft Engineering Corporation, New York, N. Y.....	3,484.65	41,815.80
Wittemann-Lewis Aircraft Co., Newark, N. J.	3,400.00	40,800.00
L-W-F Engineering Co., Inc., College Point, L. I., New York.		
Wooden landing gear	996.50	11,958.00
Nickeled steel landing gear	1,462.00	17,544.00
Continental Aircraft Corporation, 120 Liberty Street, New York, N. Y.....	2,325.00	27,900.00
West Virginia Aircraft Company, Wheeling, West Virginia.....	1,830.00	21,960.00

To Manufacture Aeroplane Parts

Newark, N. J.—John Cozzone & Co., of 61 Arlington Street, Newark, N. J., have purchased a factory site at which they are preparing to undertake the manufacture of aeroplane parts. The factory is located at 55 Branford Street, Newark.

Personal Pars

Charles B. Wilson, president and manager of the Wilson Foundry and Machine Company, Pontiac, Mich., has been elected vice-president of the Curtiss Aeroplane and Motor Corporation, Buffalo, N. Y.

Hydro-Aeroplane Garage for New York

A new venture is announced by Henry Amerman, attorney for a group of men headed by I. M. Uppercu, president of the Aeromarine Plane and Motor Company. It is proposed to build a public flying boat service station—a hydroaeroplane garage—at 181st Street and the Hudson River, at Fort Washington Point.

Mr. Amerman stated that the venture is being projected merely to encourage water flying and the private ownership of air yachts. The station will be a garage only. There is no intention of participation in passenger-carrying lines or anything of that nature other than to sell 'planes and rent hangars. However, the establishment of schools will be encouraged, as will sight-seeing airboat lines, air yacht taxi companies, etc.

The founders of the idea are hopeful that the project will be taken up throughout the country and that other plants will be established. This would be profitable as the spring will probably find many aircraft concerns seeking locations for selling agencies. It would be natural for them to choose those places already provided with municipal or privately-conducted service stations.

Cited for Distinguished Service

The Commander-in-Chief, in the name of the President, has awarded the distinguished service cross to the following-named officers and soldiers for the acts of extraordinary heroism described after their names:

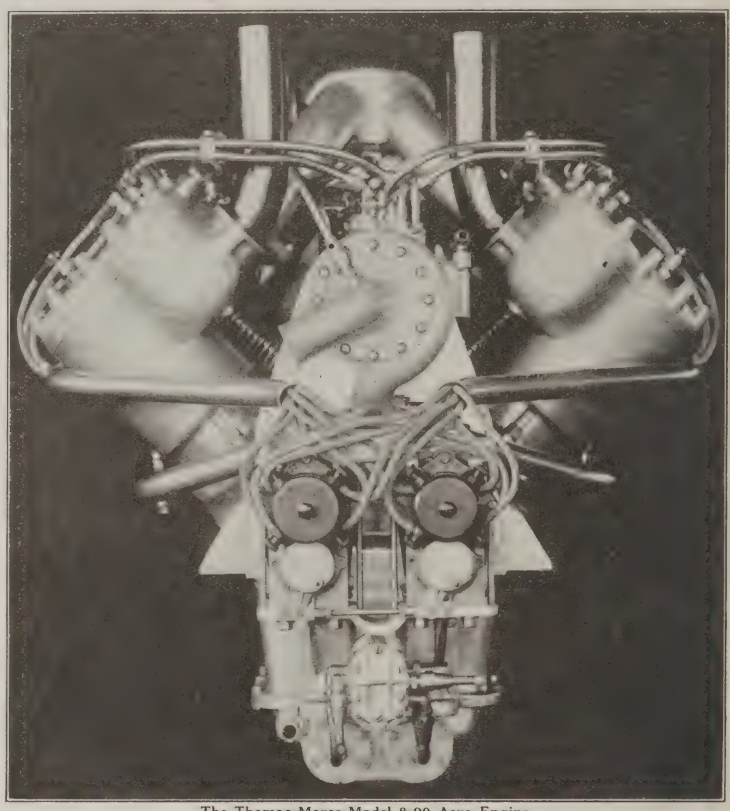
First Lieut. Elliott, White Springs, Air Service. For extraordinary heroism in action near Bapaume, France, August 22, 1918. Attacking three enemy planes (type Fokker), who were driving on one of our planes, Lieut. Springs, after a short and skillful flight, drove off two of the enemy and shot down the third. On the same day he attacked a formation of five enemy planes (type Fokker), and after shooting down one plane was forced to retire because of lack of ammunition. Home address, Leroy Springs, father, Lancaster, S. C.

Sergt. (first class) Harold O. Nicholls, Balloon Service, First Army (A. S. No. 36238). For repeated acts of extraordinary heroism in action near Griscourt, France, August 11, 1918; near Avecourt, France, October 1 and 9, 1918. On August 11 Sergt. Nicholls volunteered and ascended for the purpose of making observation. He continued with his work until the balloon was set on fire by attacking enemy planes. On October 1 he remained on duty until his balloon was fired by incendiary bullets, and again on October 9, while on duty with another observer, he remained with his balloon under attack until it was set on fire by enemy planes, and he then refused to jump until his companion had escaped. Home address, Mrs. Helen Nicholls, 1716 Avenue C, Galveston, Tex.

First Lieut. Leo H. Dawson, Air Service, 94th Aero Squadron. For extraordinary heroism in action near Hartennes, France, July 19, 1918. While on a voluntary patrol, Lieut. Dawson encountered seven enemy monoplanes at an altitude of 2,000 meters. After a brief engagement his guns jammed, but, after repairing the jam in the air and under heavy fire, he returned to the fight, shot down one of the enemy in flames and drove off the others. For the following act of extraordinary heroism in action near Clery-le-Petite, France, November 4, 1918, Lieut. Dawson is awarded a bar, to be worn with the distinguished-service cross: Sighted four enemy planes (type Rumpler); Lieut. Dawson immediately attacked, despite the numerical superiority of the enemy, and destroyed one of the group, whereupon the remaining three scattered and returned to their lines. Home address, Mrs. A. G. Dawson, 942 Ogden Street, Denver, Colo.

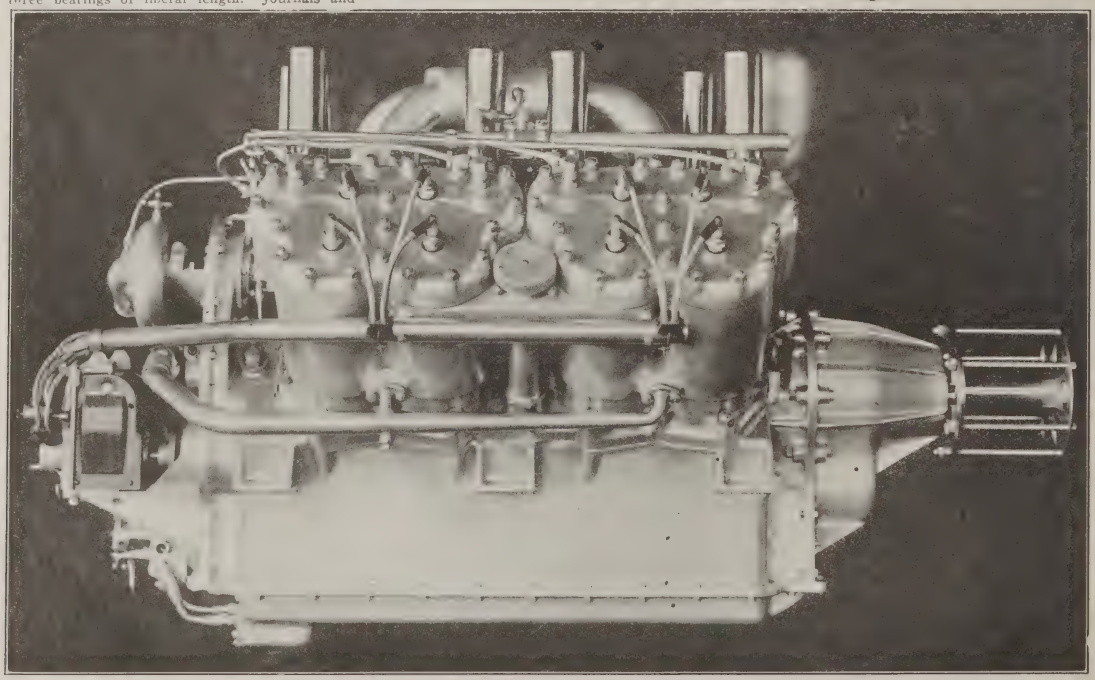
THE THOMAS-MORSE MODEL 8-90 AERO ENGINE

Type—Eight cylinder "V", four cycle, water cooled. Propeller driven through reduction gearing. Bore: four and thirteen sixteenths inches. Stroke: six inches. Brake Horse Power at propeller shaft: 250. Engine R.P.M.: 2,200. Propeller R.P.M.: 1,512. Gasoline Consumption: .54 lbs. per H.P. hour. Oil Consumption: .04 lbs. per H.P. hour. Weight of engine, complete with propeller hub, flanges and bolts, carburetor mounted, two magnetos, gasoline supply pump but without radiator, water, oil, starting device, exhaust pipes or propeller: approximately 590 lbs.



Cylinders—The cylinders are of the "L" head type. Cast in blocks of four each of special non porous, high tensile strength aluminum alloy. The integral water jackets are designed to provide ample space around all parts of the cylinder. The cylinder feet are of sturdy proportions with holding down bolts close to the cylinder barrels. The cylinder heads are bolted on, an ample number of studs evenly and closely spaced being used for this purpose. The cleaning out of the carbon and the grinding of valves and the general inspection of cylinders and pistons is thus greatly facilitated. Cast iron is used for the liners, fitted to the cylinder barrels, as no material has been found to equal it for wearing qualities.

Valve and Valve Mechanism—Valves are of Tungsten steel, made in one piece without welding and have a clear port opening of two and thirteen sixteenths inches. Valve springs are of special alloy steel to insure continuous service under the most severe conditions. The valve push rod guides are held in the cylinder feet. The push rods made of hardened tool steel are operated directly by the cams without intervening cam rockers and are provided with means for adjustment, making a light, durable and simple valve operating mechanism. Special provision prevents oil leakage at the push rods



Camshaft.—The three bearing camshaft, with its sixteen integral cams hardened and ground to size, is located in the crankcase between the two banks of cylinders. To insure rigidity and long life to the camshaft bearings, it is made of generous size and drilled for lightness. The special phosphor bronze bearings are lubricated by high pressure force feed, directely from the main oil duct. The driven end of the camshaft is flanged for bolting to the timing gear.

Timing Gears—The two timing gears, with spur cut teeth, are made of chrome nickel steel, heat treated. The camshaft gear is bolted to the flanged end of the camshaft. Lubrication is provided by overflow of oil through the pressure regulating relief valve, situated adjacent to the timing gears at the end of the high pressure main oil duct

Crankshaft—The four throw crankshaft made of special chrome nickel steel, is carried on three bearings of liberal length. Journals and

The Thomas-Morse Model 8-90 Aero Engine

The Thomas-Morse Model 8-90 Aero Engine

crankpins are two and one-half inches in diameter, drilled for lightness and plugged for the high pressure force feed lubrication system. The crank webs are also drilled and plugged to lead oil to the connecting rod big ends.

Connecting Rods—The connecting rods are of H section, arranged side by side on the same crank pin for opposite cylinders. They are made from a special grade of heat treated, chrome nickel steel, having a very high elastic limit, and are machined all over, securing exceptionally light weight and uniform balance. The big ends are babbitt lined; the babbitt being applied directly to the rods and forming an integral part of them. The wrist pins are locked in the connecting rods and swing in liberal bearings in the piston bosses.

Pistons—The pistons made of special aluminum alloy are light in weight and have well ribbed heads for strength and cooling. Two concentric lap jointed compression rings are located near the head, while one oil scraper ring is carried in the skirt. The piston pin is made of chrome nickel steel, drilled hollow, park hardened and ground to size.

Crankcase—The crankcase is a special aluminum alloy casting of deep sided section, well ribbed for strength and rigidity. The lower half serves only as an oil pan or sump and is bolted directly to the upper half.

Carburetor— Stromberg, double vertical carburetor is used, bolted to a water jacketed cast aluminum double branch manifold, serving the two banks of cylinders. All manifold bends are of large radii.

Lubricating System—The lubricating system is of the high pressure, circulating type. A gear pump located within crankcase and driven from the crankshaft timing gears draws oil from an oil supply tank located at any convenient place near the engine through a fine mesh wire screen which is integral with the pump. Oil is delivered from the pump to a main oil duct, also located within the crankcase. Drilled holes in the main bearing supporting webs, connecting with this duct lead the oil directly to the three crankshaft bearings. The connecting rod big ends receive oil through the drilled crankshaft webs and crank pins. Oil is carried up from the main duct to the front camshaft bearing and from there through the hollow camshaft to the other two bearings. The wrist pins and pistons, cams and push rods are lubricated by the oil thrown off the crank pins. The reduction gears are constantly sprayed with a stream of oil from the main oil duct. A gear pump mounted on the timing gear cover is so designed that all surplus oil collecting in either end of the oil pan is drawn off through large, fine mesh, readily removable screens and delivered back to the supply tank.

Water Cooling System—A single centrifugal water pump is driven at crankshaft speed by a steel gear meshing with the camshaft timing gear. Equal water distribution to both banks of cylinders is insured by a siamese outlet from the pump to the brass water pipes at the base of the cylinder jackets. Water outlet connections are arranged over each exhaust valve. All water pipes are fitted close to the cylinders for rigidity and economy of space. Only four hose connections are necessary with each motor.

Propeller Drive—The propeller shaft is driven from the crankshaft through the two spur gears of the highest grade chrome nickel gear steel, heat treated. It is rigidly supported on three large annular ball bearings housed in a well ribbed aluminum alloy gear case, which is bolted to the crankcase. The shaft is of exceptionally large diameter and drilled to secure light weight.

Ignition System—Two Splitdorf "Dixie" Magnetos are used, each constituting an entirely independent ignition system with two spark plugs per cylinder. They are arranged side by side and driven at crankshaft speed by spur gearing at the rear end of the crankshaft. This position insures their operation under the most favorable conditions, besides providing ready accessibility. Provision has been made to allow the use of "Dixie 84" magnetos, equipped for advancing and retarding the spark or fixed spark "Dixie 810" magnetos and hand starting magnetos.

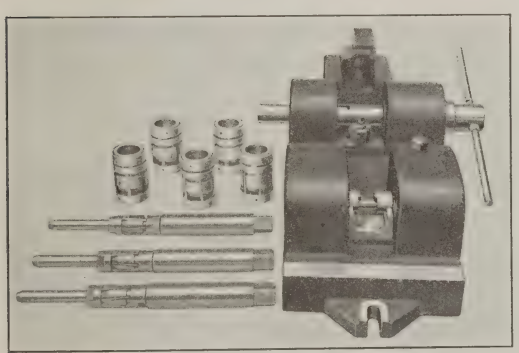
Self Starter—Provision has been made in the design for the application of the Christensen air starting system when desired. The starting unit is located between the two banks of cylinders and is driven at crankshaft speed by a steel gear engaging the camshaft timing gear. In its application to the Thomas Motor, no drive shaft is exposed, thus eliminating all chances of oil leakage. The starter is composed of four principal parts: An air pump in operation only when compressing air for storage purposes; an automatic carburetor, which supplies gasoline to the air distributed to the cylinders; an automatic distributor, which is in action during the starting period only; and a compressed air tank. The piping to the cylinders is short and direct. The entire apparatus weighs approximately 40 lbs.

Additional Equipment—A gasoline gear pump is supplied as regular equipment. It is situated near the base of the motor and is therefore gravity fed. A tachometer drive is also supplied.

LINE REAMING CRANK SHAFT BEARINGS OF LIBERTY MOTORS

By A. A. MARTELL, Chief Engineer, Taft Pierce Mfg. Co.

PUTTING the manufacture of the Liberty motor on a production basis marked a considerable step in advance of the best American practice in regard to accuracy of machine work on the component parts and also assembling the details, where unusually close limits were employed, into a smooth working and efficient engine.



Some one of our illustrious ancestors was so impressed with the value of attention to detail that he broke out in a famous poetical recital of the loss of an important battle due to the failure of a despatch bearer to deliver his message on account of a missing nail in his horse's shoe, thereby starting a train of misfortunes that resulted in a 100 per cent loss, so far as delivering the goods was concerned.

Considering the task that the aeroplane was called upon to perform, the very best we had in machinery and skill was none too good to meet the tremendous requirements.

One of the most vital parts of any motor is the crank shaft and the bearings in which it revolves. Particularly is this true of aviation motors that are continuously run with an open throttle delivering every ounce of power of which they are capable.

The accompanying cuts show the crankcase of the Liberty motor. Note the long studs that bolt the two halves together, locking them firmly and securing a great degree of strength with little weight.

The device used for these roaming bearings is shown resting in the

Connecting rod fixture for reaming

half bearings, in the same relative position it occupies when performing the actual reaming operation, which, of course, is done while the upper and lower halves of the cases are bolted together.

This reaming equipment is known as the Martell Aligning Reamer and was very successfully used on practically all Liberty motors. The operation was performed in an average time of 30 minutes per motor. The size of holes, alignment and surface of bearings passed the most rigid inspection and tests.

To briefly describe the construction of the reaming system and method of operation.

The reamer bar is made of a special steel, pack hardened, ground and lapped. It has two grooves, on opposite sides, and recesses are milled at proper intervals along both grooves to receive the ends of driving screws that, screwing through the body of the reamers, project slightly into the bore.

This bar is supported by two plain, hardened bushings, which are snugly fitted to and held in the core of the bearings Nos. 1 and 7.

To insure the perfect alignment of the bar, there are two other bushings used in bearings 3 and 5, respectively. These bushings are of special construction, consisting of two eccentric bushings, one within the other, the assembly being completed by an outer sleeve, which receives the two eccentrics. A portion of the surface of this outer sleeve is tapered and carries in fine thread, 72 per inch.

This sleeve screws firmly into the soft metal of the bearings and forms a solid anchor for the eccentrics, which are manipulated until the bar is in absolute alignment.

The reamers are then slipped on the bar, partially withdrawing it, the bar, first from one end and then the other, so that the adjustment of the centering bushings will not be disturbed.

The reaming is done by hand, as indicated by the double end wrench shown on the bar.

The design of the reamers present some novel features of construction.

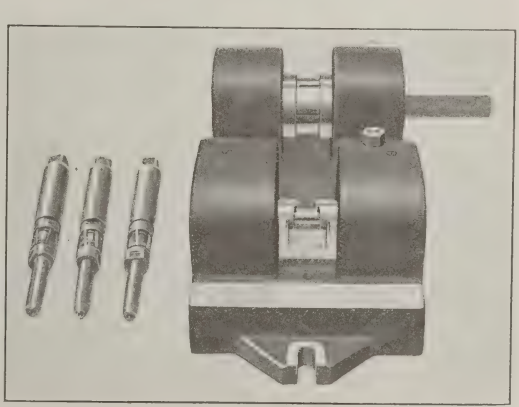
The blades, at their two ends, rest upon hardened and ground wedges, the under surface of the blades being carefully ground to the same angle as the wedges.

The blades are held firmly be means of two adjusting nuts, one at each end, whose inner edges are conically ground to receive the ends of blads which are also ground to a like angle.

There are 6 blades, 4 of them are set at a slight left hand angle in the axis of the reamer, and two are set to a corresponding angle in the opposite direction.

This disposition of cutting edges prevents chattering and produces holes that are round to within .0001.

The design of the expanding mechanism makes it possible to correct variations as small as .0002 or .0003. These corrections are easily and quickly made by simply adjusting the nuts at the two ends of blades. The rear nuts are graduated to .00025 to aid this operation.



On the Liberty motor the only means of access to the bearings was through the openings provided for the cylinders. This construction naturally handicapped the operators, and it speaks well for the loyal application of the men on the job as well as the ingenious features of the tool that they "carried on" and did their bit to take the germ out of Germany.

Reaming the connection rods presented another interesting feature, and the accompanying cuts show the method of procedure.

The illustration shows the fixture for reaming both ends of the worked rod at one setting.

A hardened and ground steel hinged clamp, accurately located, held

Connecting rod fixture for reaming

NAVAL and MILITARY AERONAUTICS

Demobilization

The War Department authorizes the following statement:

The "honorable discharge" emblem to be issued by the War Department will be a bronze lapel button somewhat similar to the G. A. R. button of like significance. It is the intention of the Government to distribute the button free of charge to all entitled to it. The buttons will be manufactured only by concerns chosen by the Government, which will furnish the dies for their manufacture and purchase the buttons, thus obviating any possible variance from the approved pattern in design, color or material.

Of appropriate and artistic design, the button is the result of a competition among American artists and sculptors, conducted by the Commission of Fine Arts, of which Charles Moore is chairman, and the following are members: Herbert Adams, J. Alden Weir, Charles A. Platt, William Mitchell Kendall, John Russell Pope, James L. Greenleaf, and Col. C. S. Ridley, secretary. Fifteen designs were submitted by the Commission for final selection by the Chief of Staff.

Overseas Troops Arriving

The War Department authorizes publication of the following:

The cruiser Frederick sailed from Brest February 19 and is due to arrive at New York March 1, with the following Air Service troops: 95th Aero Squadron, 5 officers, 165 men; 103d Aero Squadron, 6 officers, 174 men; 465 Aero Squadron, 3 officers, 126 men; 835th Aero Squadron, 2 officers, 145 men; 109th Aero Squadron, 4 officers, 126 men.

The transport Mexican sailed from St. Nazaire February 20 and is due to arrive at New York March 5, with the following troops: 2 officers, 121 men, New York; 1 officer, 130 men, Camp Upton; 23d Aero Squadron, 2 officers, 158 men; 35th Aero Squadron, 2 officers, 137 men; 149th Aero Squadron, 2 officers, 154 men; 151st Aero Squadron, 1 officer, 150 men; 153d Aero Squadron, 2 officers, 152 men; 158th Aero Squadron, 1 officer, 153 men; 173d Aero Squadron, 2 officers, 152 men; 176th Aero Squadron, 1 officer, 156 men; 184th Aero Squadron, 1 officer, 147 men; 247th Aero Squadron, 1 officer, 150 men; 264th Aero Squadron, 2 officers, 153 men; 469th Aero Squadron, 2 officers, 115 men; 374th Aero Squadron, 1 officer, 147 men; 499th Aero Squadron, 2 officers, 146 men; 500th Aero Squadron, 2 officers, 148 men.

The transport Sibone, which sailed from Bordeaux February 20 and is due to arrive at New York March 3, has on board 14 Air Service officers.

The transport Lake Gaspar sailed from Bordeaux February 20 and is due to arrive about March 8 with 1 casual officer, Air Service.

Transport Ceylon Maru sailed from Bordeaux February 20 and is due to arrive at Newport News March 7 with 1 casual officer, Air Service.

Transport Moccasin sailed from Brest February 20 and is due to arrive at New York March 4 with the following troops: 1 casual officer, Air Service.

The battleship Ohio, which sailed from Brest February 20, and is due to arrive at Newport News March 5, carries 2 casual officers of the Air Service.

The transport Buford sailed from Bordeaux February 17 and is due to arrive at Newport News March 4, with 1 casual officer, Air Service.

The cruiser Rochester sailed from Brest February 17, and was due to arrive at New York about February 25 with the following troops: 467th Aero Squadron, 4 officers and 133 men, divided as follows: 4 officers, 108 men, Camp Upton; 25 men, Camp Taylor; 1 casual officer, Air Service.

The transport Olympic sailed from Brest February 18 and was due to arrive at New York February 25 with 13 casual officers of the Air Service.

The following organizations have been assigned to early convoy: 99th Aero Squadron, Air Service Casual Co. No. 5.

Another American Ace

Lieut. J. O. Donaldson recently recommended for Military Aviator rating by the Division of Military Aeronautics' Rating Board, has been announced as an Ace, "having brought down five planes officially noted as crashes and three officially out of control." Lieut. Donaldson was not included in the first list of 63 Aces received from General Pershing; but, owing to recent confirmations from British commands with which he flew, a positive record that he brought down at least five planes is now on file in the Air Service. Lieut. Donaldson is a Washington man who took the Ground School Course at Cornell University and completed his flying training with the British. He was attached to a British Squadron when he was forced to land within the German lines. He was captured, but later escaped.

Lieut. Donaldson received the D. F. C.—the British Distinguished Flying Cross.

Preparing Air Biographies

On February 1, 1919, the Director of Military Aeronautics sent the following letter to the presidents of all universities and colleges in this country:

"The Director of Military Aeronautics asks your co-operation in the following matter, which is important to the Air Service of the country and which may be of yet more intimate concern to the locality and to the institution with which you are associated.

"This office is making every effort to assemble the personal stories of the men who have been with the Air Service overseas. It seems not unlikely that the better part of each story is contained in letters to friends and relatives at home. Letters from some of our aviators have already appeared in book form and in the magazines, and from time to time college publications have had occasion to print appreciations of fliers killed in combat.

"Such informal records may supply information of historical value to be had from no other source—information which should find a place in the written history of the country.

"The Director of Military Aeronautics therefore makes this request: That, with the full sanction of those most concerned, this office be furnished with copies of such letters, or excerpts from them, and likewise with copies of any of your student or alumni publications that have contained articles pertinent to this subject. It would be gratifying, also, if you would interest your townspeople in this matter, and would obtain the co-operation of the local press. Whatever you can do to further the assembling of this data—and with reasonable haste, that nothing may be lost—will be deeply appreciated here.

"Communications in reply should be addressed:

"Director of Military Aeronautics,
"Sixth Street and Missouri Avenue,
"Washington, D. C.

"Aeronautical Information Branch."

For a History of the War

On February 25 the War Department authorized publication of the following:

"The Secretary of War has directed that a bulletin be published to the Army to provide that officers and other persons who have served in or with the Army during the war and who are in possession of historical information of value for use in connection with the history of the war are authorized and invited to communicate such information direct by mail or otherwise to the Chief of the Historical Branch, Army War College, Washington, D. C., such material to be considered as having been furnished to the War Department unconditionally, to be used as desired and not to be returned unless request is made to do so.

"The request from the O. D. M. A. has brought assurance of co-operation from a source from which not a little might be expected. The material as received will be sifted and classified, and copies will be furnished the Historical Branch of the War College. It is desired to give all the publicity possible to this appeal from the Air Service.

"Remember, this war, too, must find its Lossing and McMaster. So officers and men in the camps who have material, in letters or other form, of the sort that goes to make histories should think to send a copy to the O. D. M. A.

"Attention Aeronautical Information Branch."

Ratings of Fliers

Major Melvin A. Hall, A.S.A., is appointed a member of the Board of Officers created by Paragraph 3, Special Orders No. 28, Division of Military Aeronautics, February 1, 1919, to pass on the qualifications of flying officers who have distinguished themselves in action, with a view to awarding them such ratings as their achievements and abilities may warrant. Major Hall is appointed vice Colonel Townsend F. Dodd, M.A., A.S.A., relieved.

Lieut. Col. Bruce B. Buttler, A.S.A., has been ordered to report at Kelly Field, San Antonio, Texas, on March 15, 1919, for examination for rating as Junior Military Aviator.

The following-named officers, having completed the required tests, are rated Reserve Military Aviators, to be effctive from the dates set after their respective names:

Second Lieut. Warren E. Calvin, A.S.A., January 20, 1919.

Second Lieut. Cyril R. Davis, A.S.A., January 20, 1919.

Second Lieut. John H. Matthews, A.S.A., February 7, 1919.

Licenses to Fly Civilian Aircraft

Licences to fly civilian aircraft issued by the Joint Army and Navy Board on Aeronautic Cognizance, up to and including February 24, 1919, are as follows:

License No.	*Issued to*	*Address*
301	Marjorie Stinson,	122 King Avenue, San Antonio, Tex.
302	Theodore Hedlund,	Boston, Mass.
303	Louis Gertson,	Chicago, Ill.
304	Baxter H. Adams,	Henderson, Ky.
305	David Gregg,	Brookline, Mass.
306	Edwin K. Jaquith,	Atlantic City, N. J.
307	Curtiss Flying Station,	Atlantic City, N. J.
308	Walter Pack,	San Francisco, Cal.
309	Leon Richardson,	Washington, D. C.
310	W. H. Fitzpatrick, Jr.,	Buffalo, N. Y.
311	Walter T. Varney,	San Francisco, Cal.
312	Clarke C. Minter,	Washington, D. C.
313	W. E. Nightingale,	Nantasket, Mass.
316	J. Riley,	Caro, Mich.
320	Harry B. Crewdson,	Chicago, Ill.
321	Warren L. Baker,	Providence, R. I.
322	Allen P. Bourden,	East Greonwich, R. I.
323	John O'Mara, Jr.,	Brooklyn, N. Y.
324	Ed R. Hutchison,	Elmira, N. Y.
326	Curtiss Aeroplane & Motor Corp.,	New York, N. Y.
327	B. H. Kendrick,	Atlantic City, N. J.
328	Prof. Rexford C. Gardiner,	Celoron, N. Y.
330	Frank Bonar,	Underwood, Iowa.
331	Charles T. Mills,	La Salle, N. Y.
332	America Trans-Oceanic Co. (David H. McCullock),	New York, N. Y.
333	Frank Mills,	Essington, Pa.
335	Walter W. Raub,	Salem, Ohio.
336	A. W. Snyder,	Bolling Field, D. C.
337	Howard A. Scholle,	New York, N. Y.
338	Melvin W. Hodgdon,	Somerville, Mass.

Licenses renewed:

License No.	*Issued to*	*Address*
117	The Lawrence Sperry Aircraft Co.,	Farmingdale, L. I.
176	Dewey Airplane Company,	Dewey, Okla.

Types of Planes Active, Obsolescent, or Obsolete

The following types of planes are declared by Circular No. 5, O. D. M. A., February 21, 1919, "active," "obsolescent" and "obsolete":

ACTIVE

Planes	*Motors*
Curtiss JN4H (JN4HB)	Hispano Suiza Model I
Curtiss JN6HO (JN4HG)	Hispano Suiza Model E
Curtiss JN7H (JN6HB)	Liberty-12
DeHaviland 4 (JN6HP)	LeRhone 80 HP
USD9A ((JN6HG1)	
SE-5 (JN6HG2)	
VE-7	
S4-C	
Martin Bomber	
Hydros	
Lepere	
Handley Page	
Spad	
Sopwith Dolphin	
Caproni	

OBSOLESCENT

Planes	*Motors*
Curtiss JN4A	Curtiss OX2
Curtiss JN4B	Curtiss OXX3
Curtiss JN4D	Curtiss OX5
Canadian JN4	Hispano Suiza Model A
Thomas Morse Scout	equipped with Gnome Motor

OBSOLETE

Planes	*Motors*
Curtiss R4	Thomas Morse -8
Curtiss R2	Curtiss Model -0
Curtiss N8	Curtiss OXX
Curtiss Twin	Curtiss OXX-2
LWF	Curtiss N-8
Standard J-1	Sturtevant 5-A
L-2	Hall Scott A5A
R-6	Hall Scott A7A
Martin -R	Lawrence

Standard D	Clerget -9
Heinrich C-1	Curtiss V-2
Aero Marine	Curtiss V-X
Boeing	Wright 6-cyl.
Martin TT	Salmson M-9
Martin R6	Renault -12
Standard H-2	Renault -8
Standard H-3	Sturtevant 4-cyl.
Sturtevant S-4	Aero Daimler 6-cyl.
Bristol Fighters	Curtiss Type S
Burgess Hydroplane	Laviateur -8

The following is the policy in regard to operation and repairs of obsolescent planes and engines:

(a) Obsolescent planes and engines will be operated and used in active training until through accident or fair wear and tear they are put out of commission.

(b) Where necessary spare parts are available at a Flying Field or Repair Depot, obsolescent planes and engines will be repaired and put back in commission.

(c) Where the necessary spare parts for making repairs are not available at a Flying Field or Repair Depot, they will be requisitioned on the supply source, which source will obtain them, if possible, from other Flying Fields, Repair Depots or Supply Depots in cases where there are none at the supply source upon which the requisition was issued.

(d) Where obsolescent planes and engines are out of commission on account of the lack of spare parts which may be easily manufactured at the Flying Fields, it will be left to the judgment of the Commanding Officer as to whether or not it is advisable to make the necessary parts to complete the repair. No extensive repairs, however, will be made.

(e) No spare parts will be purchased or manufactured other than as indicated in paragraph (d).

(f) After Surveys and Salvage Reports have been properly executed, parts from planes and engines out of commission on account of lack of spare parts will be used as spare parts for making repairs to other similar planes and engines which may be put in commission by the use of parts from the planes so surveyed and salvaged.

The policy regarding the disposition of obsolete planes will be announced later.

Flying Data

Aeroplane daily crew reports from flying fields yield some interesting summaries, according to tabulation by the Information Records Branch of the Supply Section for the month of December, 1918. Here are some of the totals for the 27 flying fields considered as one. Decimals for the larger numbers are omitted.

For All Fields

Total hrs. per mo. Engine running time	49,745
Total hrs. per mo. Aeroplane flying time	44,759
Average number ships per day	531
Total gals. gas per mo. put in	320,938
Average gals. gas per ship per hr	6.45
Total qts. oil per mo. put in	111,966
Average qts. oil per ship per hr	2.25
Qts. used oil returned	11,362

Travel for Aviation Purposes

Section III of G. O. 22 W. D., February 6, 1919, amends Section III of G. O. 81 W. D., 1918, as follows:

"Actual and necessary expenses, not exceeding $5 per day, may be paid from the Signal Corps appropriation of July 24, 1917, or from the Air Service appropriation of July 9, 1918, to officers, enlisted men, and civilian employees of the Army, and authorized agents when sent on special duty for aviation purposes at home or abroad under specific instructions from the Secretary of War."

It also announces that "Vouchers submitted for payment under the provisions of this order will be accompanied by an itemized statement of expenses."

It is to be noted that this change in General Orders has the effect of stopping reimbursement for expenses of any special duty for aviation purposes not authorized by the Secretary of War. Also, that actual expenses and not a per diem allowance will be paid, and that reimbursement will not be made for expenses in excess of $5 a day.

The officer in charge of Airship Training and Instruction at Akron, Ohio, is announced as Commanding Officer of a Balloon School, for the purpose of issuing travel orders in cases of officers, returning from free balloon flights.

The "Family Medicine Book" for Motor Troubles

A pamphlet on Motor Trouble Shooting, issued by the Training Section, has been sent to the various flying fields for the use of pilots in cross-country flying.

The compilation of this pamphlet stands to the credit of Second Lieut. Curtis C. Webb, Assistant Engineer Officer at Ellington Field, who did all the detailed work on it.

The pamphlet is a well-set-up pocket edition of about twenty pages, excellently printed and well laid out. Each "trouble" has a page to itself, where it is diagnosed in itemized form. Directions for starting Hispano-Suiza and Liberty engines and a few general rules precede.

Over 210 Hours in the Air

Ream Field boasts a JN4-H with a record of 210 hours and 20 minutes actual flying time without once having had its motor overhauled.

According to the Rockwell Field *Weekly Flight*, "this ship put in over 95 hours in combat work—conceded to be the work placing the heaviest strain on a ship—was mounted with a Marlin machine gun and used in tow target work and parachute drill, and answered in full every call on it without the mar of a single forced landing."

The chauffeur, one of Ream Field's best motor mechanicians, who was in charge of the plane throughout its entire course, was given permission to make an exhaustive endurance test of it. It was generally conceded that the machine was good for thirty or forty more hours, but the officers in authority decided that it should be stripped, the motor taken apart and photographed in detail and its history studied for the benefit of further motor construction.

Lieut. Col. William Thaw, now at Rockwell Field, has been designated Post Executive Officer.

Outstanding Contracts

The Statistics Branch, General Staff, War Department, announces the values of contract terminations and deliveries for the Army Air Service to February 8, in percentage of contracts outstanding November 9, 1918.

No allowance for settlements has been made. Value of suspensions as well as of cancellations are included in terminations.

The figures are: Terminated, 82.5 per cent.; delivered, 15 per cent.; balance, 2.5 per cent.

Recent Naval Orders

Lieutenant Louis E. Thornton, to duty under public works officer, naval air station, Pensacola, Fla.

Lieutenant (junior grade) J. R. Gibson, to duty in command of naval air station, Marginal Parkway, Brooklyn, N. Y.

Lieutenant John A. Davis, to duty as inspector of engineering material, U. S. N., Curtiss Aeroplane and Motor Corporation, Buffalo, N. Y.

Lieutenant (junior grade) J. A. Eaton, to duty naval air station, Rockaway Beach, L. I.

Lieutenant John S. Fulton, Jr., to duty office of naval operation aviation, Navy Department.

Lieutenant William B. Atwater, to duty as aviation aide Sixth Naval District.

Lieutenant J. W. Brown, to command the N-5.

Lieutenant R. D. Bussdicker, Avia., Pauillac, to Pauillac, connection Crew No. 3.

Lieutenant (junior grade) James S. Cuff, to duty U.S.S. N-2.

Lieutenant Commander W. R. Sullivan, Avia., Queenstown, to Base No. 18.

Lieutenant B. V. Eckhout, designated as Nav. Aviator.

Lieutenant P. J. Piccirilli, from Curtiss Aero and Motor Corp., Buffalo, N. Y., to duty, Nav. Yard, Washington, D. C.

Lieutenant A. Tucker, to duty in Construction and Repair Department, Nav. Station, Pensacola.

Lieutenant Edwin S. Parsons, to duty in command naval air station, Bayshore, L. I., N. Y.

Lieutenant Commander Nathan B. Chase, to duty Brunswick, Ga., report commanding officer naval air station temporary duty and for duty command upon det. of present commanding officer.

Lieutenant W. T. Hopkins, Avia., Brest, to Base No. 7.

Lieutenant Julian A. Ducray, to duty as executive officer naval air station, Miami, Fla.

Lieutenant Commander James C. Monfort, Naval Air Station, Rockaway, L. I., as executive officer.

Lieutenant (junior grade) James S. Cuff to U. S. S. N-2.

Lieutenant Commander Harold C. Van Valzah, to Miami (Fla.) Naval Air Station.

Lieutenant Thomas R. Cooley, to rejoin U. S. S. Florida.

Lieutenant Lyman K. Swenson, to U. S. S. R-17.

Lieutenant Lewis J. Strecher, to U. S. S. R-2.

Commander William B. Waite, Jr., to R-S, at New York.

Lieutenant Scott Umsted, to command U. S. S. N-2, on detachment of Lieutenant Commander Frazer.

Lieutenant Alva J. Moore, to duty U. S. S. R-3, and on board when commissioned.

Lieutenant Commander Charles M. Elder, to duty U. S. S. R-6, and in command when commissioned.

Lieutenant Benjamin H. Page, to command U. S. S. N-3.

Lieutenant (junior grade) Walter S. Mallory, to duty U. S. S. N-1.

Lieutenant (junior grade) Richard T. Guilbert, to duty U. S. S. A-4.

Lieutenant (junior grade) Roderick T. Smith, to command U. S. S. D-2, upon detachment of Lieutenant Chambers.

German machines turned over to the Allies under the armistice terms

FOREIGN NEWS

Royal Air Force Making Observations for Transatlantic Flight

London.—In a few weeks box kites carrying delicate instruments will be flown from the sterns of Atlantic liners on the various routes between England and the United States. This is to be part of a world-wide plan for recording conditions in the upper air, says the Daily Mail.

The kites are owned by the meteorological section of the British Royal Air Force. They are expected to fly at a great height and to furnish information of incalculable value to prospective transatlantic aerial pilots.

Italian Aeronautic Mission to Argentina

According to information received in Buenos Ayres, an Italian Aviation Mission, composed of four officers and several aeronautic experts, is leaving for Argentina to assist in the development of military and commercial aviation.

Dagoberto Godoy Flies Over Andes

Dagoberto Godoy, a Chilean aviator, flew from Argentina across the Andes to Chile on December 19 in a Bristol biplane. An altitude of 17,300 feet was attained during the flight. The Chilean Government has awarded a prize of 50,000 pesos (about $18,000) to the first aviator accomplishing this feat. The Military Club tendered Godoy a sumptuous banquet in celebration of his feat.

Prince Albert to Qualify for His Wings

Prince Albert of England, who for some time has been attached to the Royal Air Force and has made many flights as a passenger, is going to complete training for his wings at R. A. F. Headquarters at St. Andree, 45 miles from Bologne. A special Avro 504 type machine has been built and flown to the field from the Avro factory at Hamble.

Aerial Transport for Africa

A company has been organized in London for the establishment of aerial landing places and hangars and for the manufacture and sale of aircraft in Africa, having a capitalization of $3,000,000 and bearing the name of Aircraft Corporation of Africa, Ltd.

Looping Record Reported Broken

Issoudon, France.—Lieut. Joyce, of the testing department of the Third Aviation Instruction Center, is reported in *Plane News* as having executed 300 consecutive loops in 66 minutes. The feat was performed in a Morane monoplane with a 120 h.p. Le Rhone motor, an average altitude of 2,000 feet being maintained. 24 minutes 30 seconds were required for the first hundred loops, 20 minutes 30 seconds for the second hundred and 20 minutes for the third.

Handley Page Transatlantic Plane Being Shipped to U. S.

London.—According to a dispatch to the *New York Sun*, the Handley Page firm is packing a plane for shipment to the United States, to attempt the flight across the Atlantic from west to east. The plane is a four motored machine, propelled by four Rolls-Royce motors, totalling 1,500 horsepower and giving a speed of ninety-five miles an hour on a consumption of sixty-two gallons of petrol per hour.

Sweden Plans London to Petrograd Route

Captain Dahlbeck, a Swedish aviation expert, in an article in a Swedish commercial journal, submits a plan for a commercial air route between London and Petrograd. He points out that such a route is practicable by way of Amsterdam, Esbjerg, Copenhagen, Stockholm and Helsingfors. An alternative route through Christiania, Gothenburg and Copenhagen is also suggested for investigation.

Air Lines to Link British Dominions

London, Thursday, February 20.—"Preparations must be made for the day when all-British air routes will play a great part in the maintenance of the commercial existence of the British Empire," said Major-General Sir Frederick H. Sykes, controller general of civil aviation, in an address before members of the Australian and New Zealand Luncheon Club to-day. He said that the British government had for some time been engaged in mapping out stages on an air route from Cairo to Australia, by way of Karachi, Singapore and the Sunda Islands.

"The establishment of postal service by aeroplane is a practical proposition," he said, "and it is one the dominions will undoubtedly have in hand at an early date. Statistics show that for ten years before the war an average of £3,000,000 in gold was anually sent to the United Kingdom by Australia. I leave it to you men of business to estimate the enormous gain that would be secured if this bullion could be transferred and put into circulation in, say, ten days instead of sixty."

Sir Frederic outlined the work that is being done in establishing aerial postal routes between England and France and between Boulogne and Cologne, where British troops are located. At present a letter is five days in transit between London and Cologne, and the speaker declared this time could be reduced to seven hours. He said a regular time table is now being made out, landing stages are being fixed, and detailed preparations for the service are making progress.

British Airship Flies 5,000 Miles

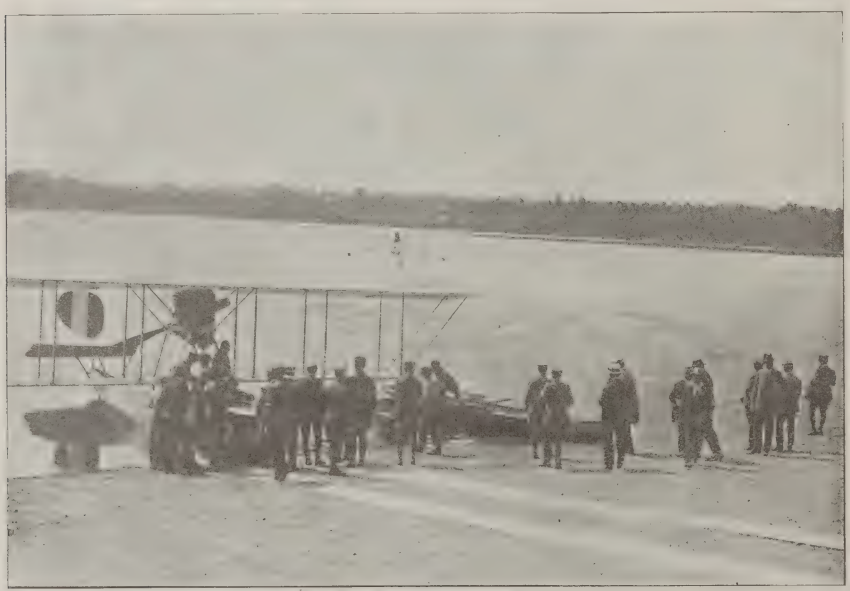
London, February 21.—During a discussion of the Aerial Navigation Bill in the House of Commons to-day, Major Gen. John E. B. Seeley, Parliamentary Under Secretary of the Ministry of Munitions announced that the Government intended to make flying safer by providing a large number of aerodromes, some of them military establishments and some civil.

A British airship, according to Gen. Seeley, recently remained in the air for more than one hundred hours. At an average speed of fifty miles an hour, the Under Secretary added, the airship must have covered more than 5,000 miles. It was possible that the airship could have continued longer in the air, the speaker declared, notwithstanding the fact that it encountered considerable wind.

Four Air Lines Selected by Great Britain for Transatlantic Flight

London.—In connection with the meteorological survey and other preparations for the early crossing of the Atlantic by aeroplane, it has been announced that four routes have been selected for the feat, as follows:

1—From Scotland to Greenland, thence to Canada.



2—From the west of Ireland to St. Johns, where the landing place for the giant seaplane, that is to make the flight has been selected.

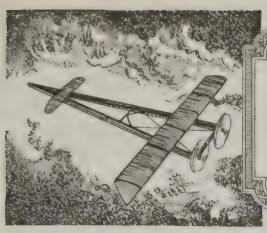
3—From the west of Ireland direct to New York, when the British fleet makes its intended visit to New York after the signing of the peace treaty, probably in July. The warships will proceed in a long line, with intervals of thirty miles between them, so as to be in position to render every possible assistance to the aeroplane crossing the ocan.

4—By way of Cornwall, Portugal, the Azores and thence direct to New York.

Vedrines to Fly Caudron to Rome

Paris.—Jules Vedrines, who recently landed on the roof of a Parisian Theater, the Galeries La Fayette, announced his intention of flying a twin-engined Caudron on a non-stop journey from Paris to Rome and back. The machine is of the type known as C23, officially, a pattern of night-bomber intended for the entertainment of the Berlin populace during the long mid-winter evenings. The armistice, however, made this unnecessary. The C23 Caudron planes are equipped with two 300 h.p. Hispano-Suiza engines and have sufficient lifting power to carry a twenty-four hour supply of fuel. It is quite possible that Vedrines will succeed in breaking the world's endurance record.

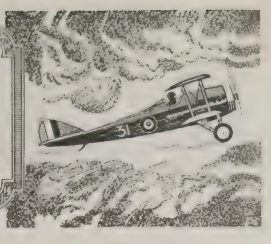
Two F. B. A. Flying Boats ready for flight



British Lighter-Than Air Anti-Submarine Patrol

London.—The London *Times* aeronautical review reveals several facts of interest regarding the lighter-than-air patrol against the submarine. A chain of lighter-than-air bases was established on the coast, from Mullion in Cornwall around the coast of England and Scotland to Pembrook. In this patrol and convoy work conducted from these bases, a total of more than 53,554 hours was flown. One of these flights lasted 50 hours and 55 minutes, which record has been bettered by ten hours since the signing of the armistice.

The airships used were of six types: S. Ss. (Submarine Scouts); S. S. Ts. (Imprvoed Submarine Scouts with two motors); Coastals, Coastal Stars, Parsevals and N. Ss. (North Seas).



London to Glasgow Airline

London. — Grahame White has announced that a daily London to Glasgow express air service is being established.

ELEMENTARY AERONAUTICS *and* MODEL NOTES

By John F. McMahon

Three Cylinder Motorcycle Driven Machine

AS stated last week I am about to describe a light one seater medium fast motorcycle engine machine or at least an improved motorcycle engine with 3 cylinders. Before proceeding I might suggest that readers who contemplate building this machine should subscribe to this paper to insure against missing one or more of these articles which is generally the case when a reader depends on getting one from a local newsdealer.

Hundreds of letters have been received asking for back numbers of AERIAL AGE containing an article pertaining to the Ford motored aeroplane only to be refused on account of these numbers being exhausted. The reader can send his subscription to the Model Editor who will see that he gets his name placed in time for the first issue containing these series.

The weight of the body of this machine will be about 75 lbs., including gas tank, seat, and control levers, as well as landing gear. The planes including struts and wiring will weigh 65 lbs. Tail works and rudder weigh 20 lbs. which gives a total of 160 lbs. The motor will weigh 125 lbs. complete, giving us a grand total of 285 lbs. for the complete machine.

These weights can be checked up by the reader as we go along. This is not difficult as wood weighs a certain number of pounds per cubic foot according to the species.

Spruce	weighs 25 lbs. per cubic foot.
Pine	weighs 25 lbs. per cubic foot.
Fir	weighs 28 lbs. per cubic foot.
Ash	weighs 39 lbs. per cubic foot.

A pound or two can be added to this if the lumber is purchased from an ordinary moulding mill or lumber yard as wood found in these places is generally not as dry as one would find in a big Aeroplane Factory where nothing but the best of materials is purchased.

To calculate the weight of the wings and fuselage is simple and the reader can do this by finding the volume of each strut and longeron or wing beams and ribs, the same as any school boy figures the amount of water that is contained in a vessel of certain dimensions.

The weight of the machine is 285 lbs. empty, for the pilot we will allow 175 lbs., and 5 gallons of gas or roughly 40 lbs. This gives us 500 lbs. approximately for the machine ready for flight.

Now we will use the R.A.F. No. 3 wing section which has a lift coefficient of .00347 at 15°45′.

To find the surface needed we simply use the formula which was given in the early issues of these articles which is

$$\text{Area} = \frac{500}{.00347 \times 1225} = 117 \text{ sq. ft. of surface needed at}$$

35 M.P.H. This you will understand is for a monoplane wing having no interference. Biplane interference varies according to the gap to chord ratio which for the combination we are going to use gives us an efficiency of 85 per cent.

As we need 117 sq. ft. of monoplane surface it will be necessary for us to increase the Biplane surface until the lift equals that of a monoplane of 117 sq. ft. We find this by dividing 117 by .85 which gives us 137.5 sq. ft. needed. At 4 degrees the coefficient is .00175.

The machine which I am about to describe will have dimensions as follows:

Top Wing	20 feet
Lower Wing	16 feet
Chord	4 feet
Gap	4 ft. 3 in.
Overall length	15 feet

There will be a single set of struts on each side and the top wing will have an overhang of 2 feet. The planes will have a stagger of 12″. Ailerons on top wing only.

Model Aeroplane Contest in California

THAT the Western boys are beginning to catch up with the boys of the East is shown in an account of flights performed by rubber driven models in a contest for a Silver Cup held by the San Francisco Model Aero Club, under the auspices of the Pacific Aero Club who are to adopt the smaller organization as an auxiliary. Mr. Sydney Bibero represented the Pacific Aero Club, of which he is secretary. The judges were Messrs. W. F. Hopkins, George Ashley and Clion Calwary.

Those who competed were the following:

Roy Ashley	Laurence Pinkham
Lawrence Irwin	Earl Vival
Daniel Tuthill	Clion Calwary
Theodore Morse	John Gutman
George Ashley	Edward Mosone
Preston Hopkins	Raymond Hasen
George Mullins	Jack Fairfield

Many members did not compete owing to the rainy weather. The contest was won by Edward Mosone. Record of flights will be printed later. Mr. W. F. Hopkins is the Director of the Club, and Raymond Larsen is President.

The rules for the contest were as follows:

1. Model must be manufactured by member entering same.
2. Each member must abide by the rules and regulations and decision of the judges.
3. Models must be flown by members entering same.
4. All entries must be registered before the flight: name of exhibitor, type of model, and weight.
5. Each entry is entitled to three trials and three official flights.
6. Announcement must be made to judges before each official flight is flown. Official flights must not be flown before word from the judges.
7. Each entry is allowed two assistants.
8. No flight is conceded official unless the model flies 100 feet.
9. Flights will be measured in a straight course, regardless of curves, dips and circles.
10. Judges may change regulations at their pleasure.
11. The average feet flown declares the point. The winner of the contest is declared one point toward the cup.

The San Francisco Model Aero Club holds contest for a cup. Mr. R. Hansen is fourth from left standing

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

The Soliloquy of a Modern Hamlet

To fly, or not to fly—that is the question.
'Tis not befitting that we stand aloof—and
In the aerial fields we pioneered—see
Other nations plunged in contest keen
To wrest the laurels of the skies
That, once, were ours,—to be but cast aside
As trifling baubles nothing worth.
Much better that we gird ourselves anew
And, in the lists, compete for what is but our own
By right of heritage, and in accord
With hist'ry's records of ambitions won and held
In every sphere where skill of men count aught
And Progress holds its sway.

One fain would ask how 'twas we failed
To heed the deeds and pleas of those, our pioneers,
Wrights, Curtiss, Martin,—others who saw,
Writ large on backgrounds of celestial blue,
The warning prophecies of coming days.
Yet we lay dormant. Men of other lands
Foresaw the uses of the bird-like thing
Conceived and born beneath our flag
But fostered 'cross the seas, while we
Inert, supine with smug contemptuous mien
Cared nothing for our passing fancy's child.

So came grim Mars—in tragic, fearsome garb of modern cut
And tailored by the hand of science in callous style,
And brave men fought on land and 'neath and on the sea, and—
As if in irony to mock us—
High in the clouds where we have staked our claims,—
And quit them as if 'twere barren soil
And yielding naught but Death to trespassers.

Two years,—And then the call to Freedom's standard
Rang throughout our land, and Freedom's sons responded
As in other days. Each to his bent—on sea or in the trench—
And many sought adventure in the skies
Beside their fellows—gallant Lafayettes who'd scorned
The niceties of warring etiquette—
And played their parts
The men were ours, but not the craft they flew
That helped their winning—thus they won
With Yankee grit plus skill of European design
And we would fain have had that winning all-American.
And so we paid the price of indolence that left a blot
'Pon 'scutcheon bright that ne'er before
Was tarnished by so gross a fault 'gainst our traditions.

Thrice-blessed Peace, wrought by our help
(As Saladin's Crusaders of the long-gone times)—
And with intent to prove our might in other fields
Than those of skill and wit and money-getting—
Spread out her wings and a war-tired world
Set to the task of counting up the cost
And make best use of lessons learned,—and found
That fashioning of plowshares from swords a-rust
Has counterpart in aerial craft of war
For needs of Peace in varied form and use.

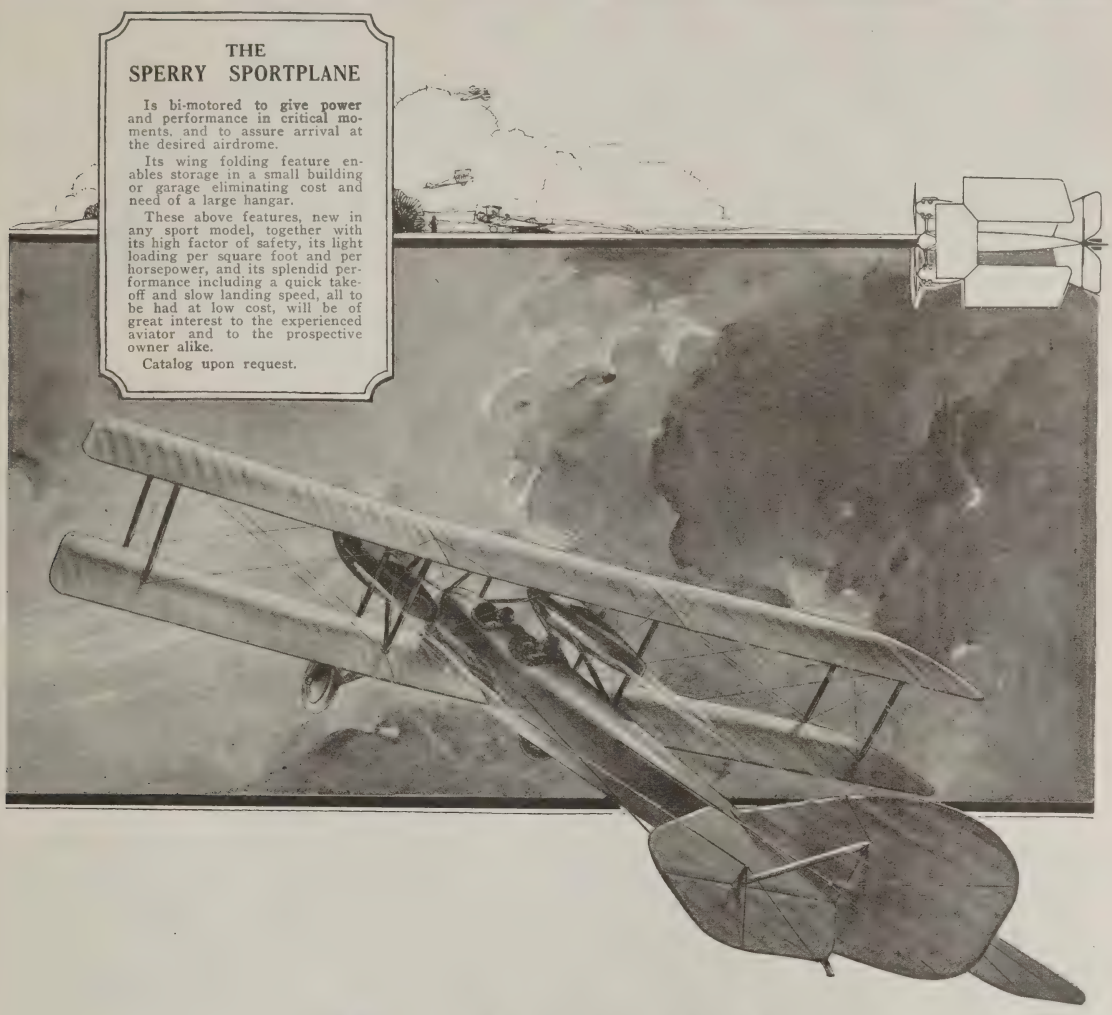
Where rests the fault that we—who should be first—
Are still alacking (in most grievous shape) that
Enterprise that needs must be applied
To gain the mastership in such directions
And so compete with those who headway made
By reason of our own short-sighted ken
And yet make headway while we—again—
Withhold the aid from those who strain at leash
To join the friendly fray of import grave?

Blame not the Press—that ever-ready friend
Of Progress in whatever guise assumed—
Nor yet our youth, well-learned in art of flight,
Awaiting but a chance to prove their worth
In fields of Commerce—as was proved in War—
On aerial highways knowing neither bounds nor fence.
Blame not our craftsmen, keen to test their skill
Against all comers in design and build
To factor conquest of the elements aloft.
And—still again—there rests no blame with those
Whose workshops idle lie and wait that wide demand
Accorded luckier rivals o'er the seas.

Where then lies the fault?,—ah, there's the rub.
To end this talk of good intent and high ambition
And let the skies bespeak that laggardness has ceased
Would be—indeed—becoming more our prestige won by deeds.
And held by greater deeds.
Much better that we know and talk cold truth,
And face the fact that contest must decide
Where—from the race-tracks of the Heavens—there comes
The shout,—"They're off!—and Europe holds the fields"
And we talk on, of trans-Atlantic flight and Polar quest,
(Great ambitions,—but scarcely all that's to 't)
And Aerial Mails,—that needs must wait awhile, forsooth,
While Europe with her far-flung sky routes laid
O'er wide dominions, linking distant colonies and sons
With Mother-lands,—and with but little said in boast.

And Europe knows—and steels herself to meet—
Our grim determinings, when aroused,
In making war or tilting in the lists of Peace
And that, eventually—
Eventually!—out upon the word—
Why not NOW?

HARRY E. TUDOR, in the Brooklyn *Daily Eagle*.



(Dedicated to those, who—with heart and mind and hand—are ready to make full amends for a fault not theirs.)

The W. B. Aeromotor

WE are ready to fill single or quantity orders for this remarkable little motor which is the product of investigation and development thruout the war.

It is a four cylinder, V type, air-cooled 129¾ pound motor developing 38 horsepower.

Besides our exhibit at the Aero Show, we will demonstrate, by appointment at a place convenient to the Show, its simplicity of installation and upkeep and its reliability of operation.

LAWRENCE SPERRY
President
THEODORE ARTER
General Manager

THE LAWRENCE SPERRY AIRCRAFT COMPANY.

FARMINGDALE, LONG ISLAND

plane and balloon fabric on Government specification, and which contributed a good proportion of the national output, had on exhibit a complete fabric-testing laboratory. One machine automatically performed and recorded tensile strength tests of fabrics while another machine made bursting tests, which were automatically recorded by the device.

This company has brought out a cotton fabric for use on aircraft which is superior to linen in that it has the same stretching characteristics as possessed by dope, thus preventing peeling and cracking. This material, known as Warwick Seamless Aero Cord, has 35 to 40 per cent. less stretch than linen, although it weighs no more than 3-ounce linen fabric. It is built up on the same principle as the automobile cord tire. A heavier weight—5.75 ounces—of this fabric withstands a bursting test of 50 pounds and possesses 300 to 400 per cent. greater strength than the cotton fabric which was first developed as a substitute for linen.

WYMAN-GORDON COMPANY

(Garden, Space 320-321)

The Wyman-Gordon Company are exhibiting their extensive line of crankshafts, which have been used on Liberty motors, Rolls Royce, Curtiss and Alberto motors, manufactured by the Fiat Company, also on the British B. H. P. and numerous others. The product of this company is well known to the industry and their extensive manufacturing experience and production facilities has enabled them to render exceptional service in supply of materials for the war program.

The Zenith Exhibit

The Zenith Carburetor Company, who, with their French, English, Italian and American factories, supplied a large majority of the carburetor equipment for the Allied Air Forces, will have an exceedingly interesting and instructive exhibit in space Nos. 101, 102 and 103, on the elevated platform at Madison Square Garden during the Aeronautical Exposition.

The Zenith Company supplied all the carburetor equipment for Liberty engines and their product was also used on such other engines as Hispano Suiza, Curtiss, Renault, Lorraine-Deitrich, Salmson, Anzani, etc. Their carburetor exhibit will consist of the following models:

US52, used on Liberty 12-cylinder aircraft engines.

US52 in section, exposing the jets, fuel and air passages, etc., so that its principle of operation may be easily explained and grasped.

US52, cut away so that the action of the altitude correcting device can be clearly seen.

48DC (French design, but American built), used on 150 H.P. Hispano Suiza.

58DC (French built), used on 220 H.P. and 300 H.P. Hispano Suiza.

65TE (French built), used on Salmson Radial engine.

55GD. This is the latest development in Zenith aeronautical carburetors, it having been approved and accepted after careful and thorough tests for the 8-cylinder Liberty engine. It was later to have replaced the US52 on the 12-cylinder engine. The signing of the armistice stopped all work on this and it was never actually put into production, although quite a few were manufactured to be used on the 8-cylinder engines completed.

L8A, used on Hall Scott 4-cylinder engine, and now used on Union Gas Engine Company's aeronautical engine.

06DS, used on Curtiss OX and OXX engines.

06DS. Sectional model showing all parts and operation.

The Zenith Company also have a very interesting and instructive booklet descriptive of the Liberty engine and of the Liberty engine carburetor. The operation of the carburetor is carefully and clearly explained, some data on the Liberty engine is set forth, and there are some very interesting photographs. These pictures include views of the carburetor, of the Liberty engine, of the first plane in which a Liberty engine was mounted, an L. W. F. specially built for the purpose, the testing outfit used on Pike's Peak, etc. These will be had on request at the exposition.

Zenith Carburetor Company representatives at the exposition: V. R. Heftler, president and general manager; V. I. Shobe, assistant general manager; L. A. Pratt, advertising manager; R. H. Taylor, New York branch manager; C. C. Sands, road engineer.

Specialized Wood-working Machinery Unnecessary for Making Aircraft Parts

It is the general opinion that large investment in new machinery is required if a joinery or cabinet work plant is to turn to making small aircraft parts. While highly specialized machinery for making finished parts have been designed and are of great value in quantity production, the equipment of a small wood-working factory is frequently sufficient to produce profitably such parts as wing beams, ailerons, struts, elevators, and landing gear parts.

A British contemporary publication lists the essential machinery for the production of such parts as follows:

Circular saw
Surface planer } May be a combined machine.
Thicknesser

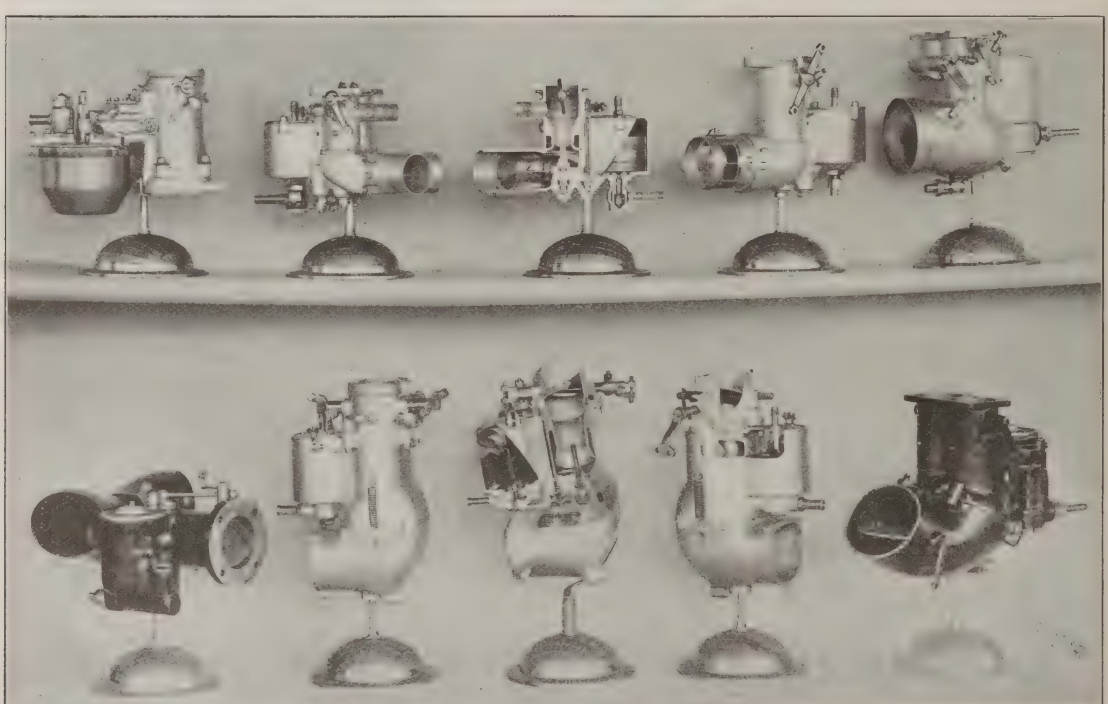
Band saw
Jig saw
Two double spindles
One single spindle
Dimension saw
Drilling machine.

There may not appear sufficient machines above, but it is quite practical to recess or box spars on a single spindle. Although it may appear a delicate undertaking, the article produced is smooth enough to be left without further cleaning up, apart from papering the stop of the cut.

Also struts may be spindled in a box or jig very simply constructed and do not take longer to clean up and finish than those made on a copying lathe or strut-former.

The manufacture of propellers has proved very profitable to some sub-contractors, and only requires machinery available in almost any wood-working mill. In addition to the machinery listed below, if four blade propellers are to be produced a tennoning machine is required for half lapping.

Band saw
Surface planer
Thicknesser
Double spindle
Light drilling machine for pilot hole
Heavy drilling machine for hub and bolt holes.



A good deal of shaping with only the above equipment is necessary, but only where there is production in considerable quantities is any material saving effected by recessing machines and the like, as the original investment required is large.

It has been frequently demonstrated that greater attention to the salvage of waste material is sufficient to make profitable the employment of a good man with the sole duty of watching and advising on the conversion of timber during its passage through the saw mill.

Weather Does Not Affect Liberty Motor

Captain J. L. Robinson, who flew from Detroit to Ellington Field, Houston, Texas, in a De Haviland Four plane equipped with a Liberty motor, is quoted as stating that the Liberty motor operates as efficiently in zero weather as in summer weather.

Captain Robison, accompanied by Lieutenant A. A. Adams, is making cross country flights to make technical observations of the Liberty motor under winter flying conditions. On January 3rd to 4th they made a flight from St. Louis to Indianapolis to Detroit, and although the weather was below zero it was merely necessary to renew gas and oil to make the plane ready for the long southward flight.

(Madison Square Garden)

Liberty Starter

Approved and Now Being Made For U. S. Naval Hydroplanes

Weight, 49 pounds complete.
Cranks motors up to 500 horsepower.
The device itself weighs but 30 pounds.
It is entirely self-contained without brackets or other gearing, bolting direct to crankcase of engine, and cranking direct to end of crankshaft.

A small air cylinder, 1¼" x ¾" with piston running continuously for air pressure on gasoline feed tank is combined with the device and entirely independent in action. This starter furnished with or without it at option.

Official Tests All Satisfactory

CURTISS AIRPLANE CORPORATION
April 20-22, 1916

HALL-SCOTT MOTOR COMPANY
Dec. 6-7, 1916

WASHINGTON NAVY YARD
Aeroengine Testing Lab.
Oct. 23-24, 1917

LANGLEY FIELD
May 15, 1918

Information regarding these trials given on request.

THE simplicity and reliability of the Liberty Starter for Airplanes are due to the fact that compressed air, the most reliable and easily controlled motive force known, is the actuating energy.

Where chances of starter trouble cannot be taken, as, for instance, on naval seaplanes, this type of starter is equipped. Liberty Starters have been thoroughly tested by the U. S. Navy, and are used on U. S. Naval Planes. (See list of tests made.)

The Liberty Starter is an air motor for starting, and a compressor to store air for its own energy in starting. It is entirely self-contained; couple direct to end of crankshaft of motor; needs no alteration in motor or gear reduction, and has ample power for magneto starting. It is the *one* efficient, *dependable* type of starter for airplanes to-day.

We welcome comparative tests, and will gladly arrange for any kind of trial for the Liberty Starter.

STREAMLINE WIRE VS. CABLE

THE superiority of streamline wire over cables for the rigging of aeroplanes is shown in some interesting comparative flying tests made at McCook Field, Dayton, Ohio, on November 15 and 25.

A De Haviland 4 plane was equipped with streamline wire and its performance compared with a similar machine having cable.

The results are as follows:

	—With Cables—		—With Streamline—	
Altitude (feet)	Speed M.P.H.	Engine R.P.M.	Speed M.P.H.	Engine R.P.M.
5,000	122.0	1,700	126.0	1,680
6,500	121.0	1,670	125.5	1,670
10,000	118.5	1,620	124.0	1,620
13,000	115.0	1,570	122.0	1,680
15,000	110.5	1,540	119.0	1,540

Speed with cable at 15,000 ft. is low.

Average increase in speed attained is 5.5 M.P.H.

With reference to mention of increase speed attained of 5.5 miles per hour, this is an increase over the use of cables covered with rubber streamline, which in themselves increased the speed about 8 miles per hour, making a total increase through the use of Hartshorn streamline of about 15 miles per hour.

A detailed report of the flight test has been made by Mr. A. J. P. Bertschy, A.M.E., of the Airplane Engineering Division, by direction of the Director of Production, B.A.P.

The report dated November 15, 1918, telling of the test flight of a De Haviland 4 plane equipped with streamline wires, is as follows:

"At 11.34 A. M. to-day, DH-4 Ship P31 Serial No. 32086 took off McCook Field in charge of Pilot Hambly with Lt. McCoy as observer for the purpose of testing streamline wires made by the Stewart Hartshorn Company.

"This ship was equipped at McCook Field with wires and fittings in order to check wire lengths, strap ends made by the Stewart Hartshorn Company and strainer plates made by the Dayton-Wright Airplane Company. The assembly consisted of double streamline fiying wires and single streamline landing, drift, interplane and tail unit brace wires. All of the measurements check correctly with blueprints and the assembly was completed without trouble. Dihedral, incidence and stagger angles were according to specifications.

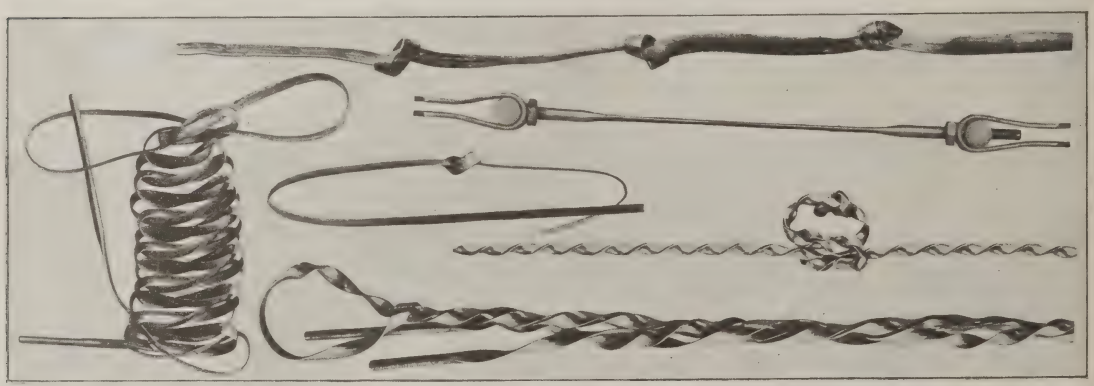
"The first 5,000 feet elevation was obtained in 3 minutes 40 seconds; highest altitude reached, 16,000 feet. The ship landed again on the field at 12.12 P. M., having been in flight approximately 40 minutes. Upon landing, all wires and fittings were found to check up correctly with all measurements taken before the take-off.

"Pilot and observer report: Noticeable increase in climbing and flying speed, as will be noted in reports when curves from indicators are plotted and computed. The air speed indicators used have been checked with the ground course; no speed test was made to-day on account of unfavorable conditions. The temperature recorded at highest altitude was 24 degrees above zero.

"This ship has been previously equipped with double cables which were streamline and an increase in speed of 8 miles per hour recorded. It is thought that with the streamline wire equipment a speed of from 10 to 12 miles will be recorded. The wires used were made by the cold reverse rolling method according to specifications drawn up by me covering wires for experimental purposes only and all wires made by this method should be accepted because they are superior to wires made by the old specifications. Further data and tests are attached.

"Mr. J. M. Layngm, representing the Stewart Hartshorn Company, and Mr. W. H. Radtke, metallurgist from the Pittsburgh Laboratories, who has been assisting me in the manufacture of streamline wires for test purposes, witnessed the applications of the wires, fittings and strap ends, and the final test of these parts in assembly, by flying as above reported.

"It should be stated here that all wires manufactured by the Stewart Hartshorn Company of East Newark, N. J., are of the same quality of those used to-day in the test flight, and I consider them superior to any wires made by any other process and very much superior to wires made in England. By reference to reports which are attached hereto, a noticeable improvement in all qualities in streamline wires made by the cold reverse rolling method will be noted."



Physical tests upon universal strap ends for the De Haviland 4 were recorded in a report dated August 29, 1918, submitted by Mr. J. S. MacGregor, A.E., of the Testing Department, Production Engineering Department, Washington.

The strap ends were made of B. H. P. Steel No. 2330. They were furnished to the laboratory assembled with streamline wires with the request that they be tested in tension assembled.

These tests were made by gripping the wire in the wedge of the machine and using pin connections on the straps. The failure occurred in every case in the streamline wire. The results are recorded below. An attempt was then made to break the strap ends without the use of the wires; pin connections, however, were used. Considerable difficulty was experienced in breaking these straps, but a fair test was obtained upon two, the results of which are shown in the tabulation. It will be noted that the strap ends have over twice the capacity of the streamline wires which are furnished with them.

Table of Results.

Laboratory Number	4835	4836	4837	4838	4839	4840	4841	4842	4843	4844
Specimen marked	1	2	3	4	5	6	7	8	9	10

Some interesting bending tests of the Stewart Hartshorn Streamline Cable

(*Continued from page* 1349

the large end of the rod, acting directly on the bronze back of the Babbitt lined main bearing.

The small end was held by means of a floating clamp that was securely locked when the small reamer, passed through the guides in the fixture, located the up and down position.

A Standard Martell Reamer was used on both ends, the whole operation taking only a few minutes.

The large end of the "Blade" rod was ground to size, the steel rod bearing directly on the outer surface of the Babbitt lined bearing of the "forked" rod.

As shown in the figure, this fixture was for reaming the small end only. The large end was located and held by means of an expanding bushing and tapered plug, located in bushed holes in the fixture.

The call for accuracy stimulated by the production of aircraft motors is extending all along the line. The practice of before-the-war methods is rapidly becoming obsolete in many instances, and the well known accuracy and speed of the Martell Reaming System should call for many installations in the motor field, not only for aviation motors, but passenger car, truck, tractor and marine motors as well.

(*Continued from page* 1336)

ciples of aeronautical engineering in a machine which would be scientifically correct as well as practically fitted for its function and duties. The aim of the designers was to produce a plane combining the qualities of the two types of machines then in use. On the one hand, there was the pursuit plane, with its rotary engine, having remarkable flexibility, speed and climb, but having short range of action, due to limited fuel carrying capacity, and being more or less unreliable because of the type of engine used and its light construction. For the time, the rotary motor had attained its limit in power and performance; efforts to increase its size and power and the number of cylinders were unsuccessful.

On the other hand, the reconnaissance and day bombing machines were somewhat cumbersome and considerably inferior in speed and climb, the advantage of their greater power being largely offset by increased fuel consumption and the larger size and weight of the machine itself.

Power Plant

The S. V. A. was therefore built to use a newly developed light and highly efficient stationary engine; the 200 h.p. 6-cylinder S. P. A., the superior of any rotary engine in power, reliability and low fuel consumption, without being considerably heavier. As a matter of fact, the S.P.A. is actually lighter, if the total of engine plus fuel for several hours flight is considered.

The compactness of the 6-cylinder type permitted a very small front area, and limited the head resistance.

Details of Construction

The wind resistance of the fuselage was made the subject of exhaustive wind tunnel tests, resulting in the peculiar triangular section of the tail gradually connected to the rectangular body. This possesses high aerodynamical efficiency and permits very rigid construction. The wooden frame and plywood panels are very strong and rigid and designed to allow no warping.

The system of trussing is novel and very successful. Instead of the usual system of struts and cables, involving considerable head resistance and requiring frequent adjustment and "tuning," a rigid system of stream-lined steel tubes was introduced, which makes the whole wing rigid under all conditions and assembly and disassembly very simple.

The wings are covered with a special silk "Ansine," manufactured for aeronautical purposes and doped by a special process.

The Landing Gear

The landing gear consists of a very simple and strong system of steel tubes. The horizontal member connecting the two sides and containing the axle is made of pressed sheet steel in a stream-lined frame having very light weight and low head resistance. A special tail-skid made of steel spring insures efficient braking effect in long landings. The machine is very sturdy and has a factor of safety larger than eight in all parts; and stands hard usage satisfactorily with very little attention.

It is armed with two fixed machine guns firing through the propeller with mechanical synchronizer.

Specifications of the S. V. A.

The specifications of the S.V.A. are as follows:

Wing spread	29′ 10″
Overall length	26′ 7″
Overall height	10′ 6″
Lifting surface	261 sq. ft.
Weight, empty (including 66 lbs. of water),	1510 lbs.

Motor: S. P. A.—Ansaldo—

190 h.p. at 1500 R.P.M.
210 h.p. at 1600 R.P.M.
225 h.p. at 1700 R.P.M.

Gasoline consumption—

16 gallons per hour at 1500 R.P.M.
17.5 gallons per hour at 1600 R.P.M.

Oil consumption ..... 6 lbs. per hour

The total fuel consumption is therefore about 100 lbs. per hour at full speed.

Useful Load: (a) Reconnaissance—500 lbs., distributed as follows:

Pilot and instruments	180 lbs.
Guns and ammunition	90 lbs.
Gasoline (2 hours on wide open throttle; about 3 cruising)	200 lbs.
Oil	30 lbs.
Total	500 lbs.

(b) Bombing—920 lbs. distributed as follows:

Pilot and instruments	180 lbs.
Guns and ammunition	90 lbs.
Gasoline (4½ hours wide open, about 6 cruising)	450 lbs.
Oil	35 lbs.
Bombs (3 bombs of 6" .38 diameter)	165 lbs.
Total	920 lbs.

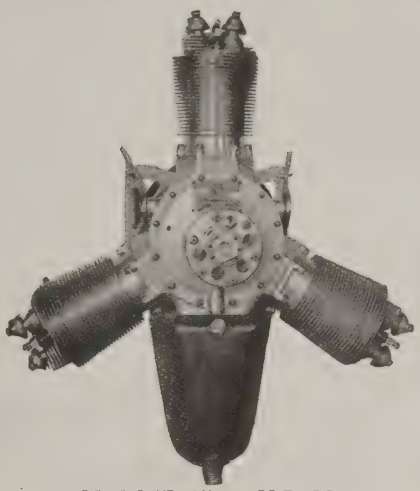
(c) In many instances and for special purposes the S. V. A. has been safely loaded up to 1,100 lbs. of useful load.

Performance:

Speed at sea-level	136 m.p.h.
Speed at 3,000 ft.	133 m.p.h.
Minimum speed	45 m.p.h.
Climb (with 500 lbs. load)	10,000 ft. in 10 minutes
	20,000 ft. in 28 minutes

The War Service of the S. V. A.

That the designers of the S. V. A. were right in their theories was apparent when the results of the static tests came within a few thousandths of an inch from the calculated; when at the first trial flights Sergeant Stoppani, the pilot, emphatically declared that no aeroplane could have better balance and manœuvring ability. It was confirmed in experimental flights and bombing trips; such as the raid, Turin-Udine-Turin, 700 miles in 5 hours by Pilot Stoppani; the raid, Malpeusa-Foggie-Bologna, 900 miles in 6 hours 50 minutes by Major Lombardo and many others.



At the front, the S. V. A. was received with enthusiasm by the pilots who found in it a machine adapted to daring expeditions over the enemy's country. The S. V. A. became the master of the Italian sky, equally dreaded by the enemy's pilots, who feared its two machine guns, and by the enemy's infantrymen, who soon knew its bombs and bullets. The remotest emplacements and works of the enemy were detected and photographed by the S. V. A.'s. Swift patrols observed the Austrian fortresses in preparation for great bombing expeditions over Pola, Cattaro, Fieume, and other cities, and returned escorting the heavy bombers, after releasing their own cargoes of high explosives. A squadron of three machines headed by Captain Polli crossed the Alps and bombed the station of Innsbrück. Another flew from the Italian front to the nest of German Zeppelins, Friedrichshafen, on the lake of Constance, and returned unharmed. Captain Polli, alone, hunting for an Austrian dirigible, crossed the Adriatic, flew all over Albania, Montenegro, Dalmatia, and returned by Trieste—about 50 miles, half of which was over the sea.

Finally, the most impressive aviation exploit of the war—the flight over Vienna. A whole squadron of 7 machines, commanded by Major Gabriele d'Annunzio, who flew a two-seater S. V. A., left the Italian front, crossed the Alps despite a storm, passed over the mountains and forests of Central Austria, reached the enemy's capital unmolested in compact formation. To the great surprise of the enemy, the Italian planes circled lower and lower over the city, took photographs at surprisingly low altitudes, dropped thousands of three colored leaflets illustrating German lies and spreading seeds of revolt. It is stated that the young Emperor Charles himself watched with fearing eyes the unprecedented and unexpected spectacle from his imperial mansion. The total distance was over 700 miles and the flight lasted about 5½ hours.

The S. V. A. Seaplane

In the meantime the S. V. A. had been modified in various forms: first, a hydroaeroplane, in

Contractors to United States Army and Navy

Model "L-1" 60 H.P. Motor
Patents applied for.

We have developed a 60 h.p. motor weighing 130 lbs. for use in small types of sport airplanes.

The same standards of material and workmanship are employed as exist in the highest class military aero motors.

Designers of aircraft should use aircraft motors—and no automobile makeshifts.

In flying the best is imperative.

LAWRANCE AERO ENGINE CORPORATION

644 West 44th Street
New York City

which pontoons take the place of the landing gear, the machine remaining unchanged in all other respects; second, a two-seater for reconnaissance and fighting.

The S. V. A. Pursuit Plane

As a result of the comment of pilots at the front, the constructors became convinced that the S. V. A. was essentially a long-distance craft adapted to endurance and speed, but it was not designed for the extreme rapidity of climb and flexibility of manœuvring required of the pursuit plane, which must be ready at all altitudes for instant combat at the first sight of an approaching enemy.

The wonderful results attained by the combination of the S. P. A. engine and the S. V. A. machine encouraged the builder to study a new type in which the successful qualities of the S. V. A. could be preserved, but the size and weight reduced, the carrying capacity limited to the fuel necessary for 2½ hours' flight, with a corresponding increase in flexibility, climb and speed. The problem was not easy, but after careful experimenting the "Ansaldo I," or "Balilla," was produced.

In this machine the wing spread is reduced and the upper wings are of same size as the lower. The motor and the pilot have been brought nearer to the center of gravity and the tail shortened, reducing the moment of inertia. With the smaller wing spread, sufficient trussing is obtained with but two struts on each side, braced by diagonal cables. A special device permits dropping the gasoline tank by pulling a lever should it be set afire in combat. The motor is then fed by gravity tank.

Specifications of the Balilla

The specifications of the Balilla are:

Wing spread	25′
Overall length	21′ 8″
Overall height	10′ 6″
Motor: Same as for S. V. A.	
Useful load (with 2 hours fuel wide open or 3 cruising)	500 lbs.
Speed	140 m.p.h.
Climb	16,000 ft. in 16 minutes

This machine had not been very long at the front before the enemy's collapse; but the results were very satisfactory, as many Austrian planes shot down by it testify.

Commercial Aspects

With the end of the war, the problems of civilian aviation comes to the front.

In this field, the S. V. A. deserves special attention, being amongst the military planes nearest and most adapted to transformation to the uses of peace. We have seen that it has been built since its inception as a long-distance plane. The greatest reliability of the engine and the plane was therefore the first consideration of the builders, and without it the machine could not have given any satisfactory service in war, where a forced landing while flying over enemy territory would have meant its complete loss.

Speed, long range and fuel economy are its main qualities. The power, while being low enough to avoid useless costs, is high enough to insure high speed, and, above all, a large reserve of power, making the handling of the plane easy and safe even through bad weather. The minimum landing speed is especially slow, and the handiness and strength of the machine reduces the damage in case of forced landing on unfavorable ground to a minimum. The operation of the machine is very economical, due to its small size, easy sheltering and handling on the ground.

In Italy it has been adopted as mail-carrier on several lines throughout the country. With the progressive spread of civilian aviation, which, though perhaps slow, cannot fail, the S. V. A. is ready to become the aerial roadster for the enterprising sportsman, in the single or two-seater types and the standard type of mailplane for the postal authorities.

Cited for Bravery

First Lieut Herbert B Bartholf, pilot, Air Service, 103d Aero Pursuit Squadron. For extraordinary heroism in action near Aincreville, France, October 3, 1918, and near Baalon, France, November 4, 1918. On October 30, in the region of Aincreville, Lieut. Bartholf, with one other pilot, engaged five enemy planes. Outnumbered, he did not hesitate to attack, and, although subjected to the severe fire of five enemy planes, he succeeded in destroying one. On November 4, in the region of Baalon, while on a bombing expedition, he encountered an enemy patrol of eight machines, Fokker type. He immediatly dived into their formation and, despite the severe fire to which he was subjected, continued a spirited combat with one of the enemy until it crashed to the ground. Home address, C. S. Bartholf, father, 535 Longwood Avenue, Chicago, Ill.

First Lieut. H. Weir Cook, Air Service, 94th Aero Squadron. For extraordinary heroism in action near the Bois de Dole, France, August 1, 1918. Sighting six enemy single seaters at an altitude of 3,500 meters, Lieut. Cook attacked them despite their numerical superiority, shooting down one and driving off the others. For the following act of extraordinary heroism in action near Crepion, France, October 30, 1918, Lieut. Cook is awarded a bar to be worn with the distinguished service cross. Lieut. Cook attacked three enemy two seaters at an altitude of 1,000 meters. After a few minutes of severe fighting his guns jammed, but after clearing the jam he returned to the attack, shot down one of his adversaries in flames, and forced the other two to retire to their own lines. Home address, Dr. B. H. Cook, father, 1327 Jackson Street, Anderson, Ind.

For the following act of extraordinary heroism in action near Fontaine, France, November 4, 1918, Lieut. Guthrie is awarded one bar; as flight commander, Lieutenant Guthrie led his formation of six planes to the attack of seven enemy stroyed, one of which was sent down by this officer. Immediately following this combat he attacked and drove off four hostile machines (type Fokker) which were about to attack one of our planes (type Fokker), six of the enemy were deballoons. Home address, K. R. Guthrie, father, care of A. T. & N. Railway, Mobile, Ala.

First Lieut. Lloyd A. Hamilton (deceased), 17th Aero Squadron. For extraordinary heroism in action at Varssenuere, Belgium, August 13, 1918. Leading a low bombing attack on a German aerodrome thirty miles behind the line, Lieutenant Hamilton destroyed the hangars on the north side of the aerodrome and then attacked a row of enemy machines, flying as low as 20 feet from the ground, despite intense machine-gun fire, and setting fire to three of the German planes. He then turned and fired bursts through the windows of the chateau in which the German pilots were quartered, twenty-six of whom were afterwards reported killed. Next of kin, Rev. John A. Hamilton, father, 25 Buell Street, Burlington, Vt.

First Lieut. Louis G. Bernheimer, Air Service, Pilot, 88th Aero Squadron. For the following act of extraordinary heroism in action near Tailley, France, November 2, 1918: Lieutenant Bernheimer and First Lieut. Ralph P. Bagby, observer, on their own intiative went on a reconnaissance mission, flying fifteen kilometers behind the German lines, securing valuable information on the condition of the bridges across the Meuse River and enemy activity in the back areas and harassing enemy troops. Home address, Sidney Bernheimer, father, 138 East Seventy-second Street, New York City.

Notable Curtiss

First commercial manufacturer of aeronautical motors in the United States.

First manufacturer of Dirigible Cars in the United States.

Invented and perfected the Hydroaeroplane.

Invented and perfected the Flying Boat.

Designed and built the OX-5 Motor—the international training motor.

Originated the famous JN-4D machine — the international training-plane.

Supplied aeronautical motors, flying-boats, aeroplanes, hydro-aeroplanes for United States, Great Britain, Italy, Denmark, Russia, Norway, Sweden, Brazil and the Argentine Republic.

Published and distributed first handbooks on aeronautical motors and aeroplanes.

Furnished instructors and instruction-data for all ground-schools and flying-fields.

Ninety-five per cent of American and Canadian aviators trained in Curtiss machines during the war.

Produced more aeroplanes than any other aeroplane factory in the world.

Largest number of commercial flying-schools in the world.

Achievements

In collaboration with Naval constructors, designed and built the largest flying boats in the world—Models T, N.C.-1 and H-16-A.

Designed and built the fastest hydroaeroplane—Model H-A.

Designed and built the fastest land-machine—Model 18-T.

Navy Air Service of the United States was 95% Curtiss design.

Designed and built the lightest high-powered twelve-cylinder "V"-type motor—the Curtiss K-12.

Invented and built first flying aerial limousine—the Curtiss "Autoplane."

Designed and built the only flying life-boat.

Designed and built the only flying fire-boat.

Largest and most modern aeroplane factories in the world.

Largest commercial Aeronautical Research Department.

Largest privately-owned wind-tunnel in the world.

Largest number of internationally-known Aeronautical Engineers on staff.

Most modern aeronautical manufacturing plants in the world.

Produced more airplanes than all other United States Manufacturers combined.

"The Birthplace of the Airplane"

WE BELIEVE in the future of aircraft in the United States. As an evidence of this belief we are exhibiting at the Aeronautical Show in New York City two Packard aircraft engines—an eight and a twelve—also a new type of plane designed by Packard engineers.

These products, as yet, are not on the market. Our purpose at this time is to do our part, along with others, in giving to the public a true picture of what the near future has in store. By so doing, we turn into useful channels the results of experience gained in producing planes and engines for war.

Packard Motor Car Company · Detroit

SECOND PAN-AMERICAN AERONAUTIC CONVENTION AND EXHIBITION

To Be Held Under the Auspices of The Aero Club of America, The Aerial League of America and the Pan-American Aeronautic Federation.

From Thursday, May 1st, 1919,
to
June 1st, inclusive,
at
Atlantic City, N. J.

CONTESTS TO BE HELD EACH SATURDAY

(1) Seaplane Contests (general),
(2) Curtiss Marine Flying Trophy and Prizes,
(3) Intercollegiate Seaplane Contests,
(4) Land Aeroplane Contests,
(5) Dirigible Contests,
(6) Kite Balloon Speed in Ascending and Descending, and Maneuvering Contests,
(7) Parachute Competition,
(8) Aviette (bicycles and motorcycles with wings) Contests.

EVERY DAY ACTIVITIES

(1) Exhibits of Aeroplanes, Motors and Accessories on the Steel Pier,
(2) Demonstrations and tests of Seaplanes, Land Aeroplanes, Motors, Dirigibles, Kite Balloons, to prospective purchasers and representatives of different governments,
(3) Aerial Passenger Carrying by seaplanes and dirigibles, and kite balloon ascensions,
(4) Moving pictures and Addresses by leading authorities on most important phases of aeronautics.

The Governments and Aeronautic, Sporting, Scientific, Industrial and Civic organizations of the United States and all the countries in the world, excepting Germany and her allies, are invited to send representatives to attend this great aeronautic event. On arrival in the United States these representatives should call at the Headquarters of the Convention Committee at No. 297 Madison Avenue, New York City, to register and receive their official badges and the official program.

In the event that it is more convenient for them to go directly to Atlantic City they will register at the offices of the Convention located at the following Atlantic City hotels: Hotel Traymore, Hotel Chalfonte, The Breakers Hotel, Hotel St. Charles, Hotel Marlborough-Blenheim, Hotel Chelsea, Hotel Alamac, Hotel Dennis and Hotel Haddon Hall.

Representatives of the Convention Committee will be at the Bureaus of the Aeronautic Convention at the above-named hotels and will issue the official badges which admit the bearer to the Aeronautic Hall, as well as the Aero Exhibition on the Steel Pier, the judges' enclosure during contests, and to the Aerodrome and seaplane stations where the aircraft and motors will be demonstrated.

All communications until May 1st, should be addressed to Rear Admiral Peary, Chairman, Aeronautic Convention, Aero Club of America, 297 Madison Avenue, New York City.

DAILY PROGRAM FOR PAN-AMERICAN AERONAUTIC CONVENTION, EXHIBITION AND CONTESTS

THURSDAY, MAY 1ST

Opening of Convention and Exhibit.

AFTERNOON—Reception at Aeronautic Hall on the Steel Pier. Addresses by United States Government State and aeronautic authorities.

EVENING—Aero Show and addresses by officials.

FRIDAY, MAY 2ND

AFTERNOON—Aero Show. Preliminary tests of seaplanes, dirigibles and kite balloons.

EVENING—Moving pictures and address on flying for sport and pleasure.

SATURDAY, MAY 3RD

AFTERNOON—Seaplane and dirigible races, and kite balloon ascending and descending contest.

EVENING—Ball.

SUNDAY, MAY 4TH

MORNING—Memorial service by eminent Divine for the dead airmen.

AFTERNOON AND EVENING—Reception to allied aces and heroes of the air and their parents, and announcement of the award of the Aero Club of America Medal of Valor, and the Aerial League of America Diploma of Honor.

MONDAY, MAY 5TH

AFTERNOON—First parachute contest for $500 Bennett Prize.

EVENING—"The Large Dirigible and Its Value for Transportation." Representatives of railroads, express, steamship and other transportation organizations invited to attend.

TUESDAY, MAY 6TH

AFTERNOON—Illustrated addresses on "Aerial Forest Patrol." Forestry Department of every State invited.

EVENING—"Work of Aerial Police Squadrons, and Why Every City Should Have One."

WEDNESDAY, MAY 7TH

AFTERNOON AND EVENING—Aerial Mail Day. Illustrated address on, and consideration of, "Aerial Mail Planes." Chairman of Post Office and Post Roads Committees of House of Representatives and Senate, and Postmaster General Burleson invited to deliver addresses. (26,000 United States Postmasters, and Chambers of Commerce of 13,000 cities invited to attend.)

THURSDAY, MAY 8TH

AFTERNOON AND EVENING—Illustrated addresses on the "Need of Municipal Aerodromes, and the Part to be Played by Aircraft in City Planning." Chambers of Commerce and City Planning Commissions of 13,000 cities invited to attend.

FRIDAY, MAY 9TH

AFTERNOON—Arrival of seaplanes and army planes from Army and Navy Air Stations. Second parachute competition for the $500 Bennett Prize.

EVENING—Illustrated addresses on "Latest Developments in Aerial Warfare and Adventures in Aerial Warfare," told by famous aces.

SATURDAY, MAY 10TH

AFTERNOON—Army, Navy and Marine Corps Day. Aerial contests and tournament.

EVENING—United States Army and Navy Officers' Reception. Reception and addresses at Aeronautic Exhibition Hall on the Steel Pier.

SUNDAY, MAY 11TH

AFTERNOON AND EVENING—Presentation of the flags by each State of the United States to the Aero Squadrons representing the States. Each State will present a flag to each Aero Squadron, the members of which were overwhelmingly natives of that State. The presentation will be made by representatives from the State and the Aero Club and Aerial League branch of that State. All States and cities invited to send delegates, and Army, Navy and Marine Corps to send representatives.

MONDAY, MAY 12TH

AFTERNOON—Demonstrations and illustrated addresses on the "Value of Aircraft for Advertising by Day and by Night." All national advertisers and advertising agents invited to attend.

EVENING—"Pan-American Aerial Transport Over Land." Addresses by members of the commissions of the 20 Latin-American Republics.

TUESDAY, MAY 13TH

AFTERNOON AND EVENING—"Pan-American Aerial Transport Over Water." Addresses by members of the 20 Latin-American Republics' Commissions.

WEDNESDAY AND THURSDAY, MAY 14TH AND 15TH

AFTERNOONS AND EVENINGS—"The Airways and Aerial Transport in Europe, Canada, Africa, Australia and Asia."

FRIDAY, MAY 16TH

AFTERNOON AND EVENING—"Aerial Navigation Instruments for Flying Over Land and Water." Aviators, navigators, scientific instrument makers and aeronautic experts invited.

SATURDAY, MAY 17TH

AFTERNOON—Aerial races and contests. Illustrated addresses on Aerial Photography.

EVENING—Extensive exhibit of aerial photographs and photographic apparatus. All photographers, professional and amateur, and makers of photographic apparatus invited.

SUNDAY, MAY 18TH

AFTERNOON AND EVENING—Illustrated addresses on "Aerial Exploration and the Use of Aircraft for Coast and Geodetic Survey."

MONDAY, MAY 19TH

AFTERNOON—Addresses on "Need of Broader Attitude Regarding Insurance for Aircraft and Aviators."

EVENING—Illustrated address on "How Army Medical Standards and Inspection Lessen Accidents." Insurance companies and agents invited.

TUESDAY, MAY 20TH

AFTERNOON AND EVENING—Illustrated addresses showing different ways of crossing Atlantic by air and the problems to be solved to accomplish same successfully.

WEDNESDAY, MAY 21ST

AFTERNOON—Aero Safety Day. Discussion of aero safety provisions made; improvements in aeroplane construction; increased reliability of aero motors; devices which make for safety in flying.

EVENING—"Progress Made in the Art of Piloting Aeroplanes." Illustrated.

THURSDAY, MAY 22nd

AFTERNOON AND EVENING—Addresses and discussions of meteorology—"How the Weather Forecasts Can be Extended and Made More Efficient by the Use of Aircraft in Exploring the Upper Air," also "How the Weather Forecasts Help Aerial Navigation," and "Telegraphic and Climatic Factors in Relation to Aeronautics.

FRIDAY, MAY 23RD

AFTERNOON AND EVENING—Addresses on "Aerial Jurisprudence—Aerial Laws and Regulation of Air Traffic." (First day.) Lawyers, traffic commissioners and police authorities of different countries invited.

SATURDAY, MAY 24TH

AFTERNOON—Races and contests.

EVENING—Illustrated address on "Need of Establishing Altitude Levels for International, Interstate and Interurban Air Travel."

SUNDAY, MAY 25TH

AFTERNOON AND EVENING—Aeronautic Art Day. Address on "Aerial Painting and Sculpture of Different Countries, and Exhibition of Aerial Paintings," by Lieut. Farre, Lieut. Ruttan and others. All prominent artists, managers of art galleries and art patrons invited to attend.

ENGINEERING WEEK.

MONDAY, MAY 26TH

AFTERNOON—"Aeronautic Engineering Problems and Their Prospective Solution."

EVENING—Opening of contests for designs and ideas for large aeroplanes.

TUESDAY, MAY 27TH

AFTERNOON—"Factors That Increase the Efficiency for Large Dirigibles."

EVENING—"Advantages of Veneer and Plywood for Aircraft Construction."

WEDNESDAY, MAY 28TH

AFTERNOON—Address on "Problems of Flying at 35,000 Feet and Over, and Their Prospective Solution."

EVENING—"Present Day Aero Engines."

THURSDAY, MAY 29TH

AFTERNOON—"Flying Boats Versus Hydroaeroplanes for Sport and Transportation."

EVENING—Contest for designs and ideas for large aeroplanes.

FRIDAY, MAY 30TH (Memorial Day)

AFTERNOON—Dirigible races, kite balloon speed ascending contest; parachute contest.

EVENING—Reception at the Aeronautic Hall, Steel Pier.

SATURDAY, MAY 31ST

AFTERNOON—Seaplanes, land planes and dirigible contests. Aviette competition at which all cyclists and makers of bicycles and motorcycles will be invited.

EVENING—"International Medical Standards for Aviators in War and Peace." Reports from different countries illustrated with attractive films. 50,000 medical men invited.

SUNDAY, JUNE 1ST

AFTERNOON AND EVENING—Award of prizes and diplomas for all events.

PROGRAMME

Deuxième Convention et Exposition Aeronautique Pan-Américaine
Sous les auspices de l' "Aero Club of America," "The Aerial League of America," et la "Pan-American Aeronautic Federation."
Du Jeudi 1 Mai, 1919 au 1 Juin, inclus. à Atlantic City, N. J.

CONCOURS DEVANT ETRE TENUS CHAQUE SAMEDI.

1. **Concours d'hydravions.**
2. **Trophées et Prix Curtiss pour Aviation Navale.**
3. **Concours Intercollegiaux pour Hydravions.**
4. **Concours d'Avions.**
5. **Concours de Dirigeables.**
6. **Concours de rapidité d'ascension, de descente et de manoeuvre pour ballons captifs.**
7. **Concours de Parachutes.**
8. **Aviettes (bicyclettes et motocyclettes munies de voiles).**

EPREUVES QUOTIDIENNES.

1. **Exposition d'Avions, Moteurs et Accessoires sur la jetée d'acier.**
2. **Demonstration et essais d'hydravions, avions, moteurs, dirigeables, ballons captifs, aux acheteurs eventuels.**
3. **Transport de passagers par hydravions et dirigeables, et ascensions en ballons captifs.**
4. **Representations cinématographiques et conférences sur les phases les plus importantes de aéronautique suivant le programme ci-dessous:—**

JEUDI, 1ER JOUR
Ouverture de la Convention et Exposition.
Après-midi—Réception au Hall de l'Aéronautique sur la jetée d'acier. Discours par des autorités du Gouvernement.
Soir—Des Etats-Unis, et l'Etat et de l'Aeronautique Exposition aeronautique et discours par des personnages officiels.

VENDREDI, 2EME JOUR
Après-midi—Exposition aeronautique. Essais préliminaires. D'hydravions, dirigeables et ballons captifs.
Soir—Représentation cinématographique et conférences sur l'aviation en tant que sport, et agrément.

SAMEDI, 3IEME JOUR
Après-midi—Courses d'hydravions et dirigeables, et concours d'ascension et de descente pour ballons captifs.
Soir—Bal.

DIMANCHE, 4IEME JOUR
Matin—Service pour la mémoire des aviateurs morts.
Après-midi, et soirée—Réception des As Alliés et Héros de l'air et de leur familles. Remise de la Médaille de Valeur de l'Aero Club d'Amérique et du diplome d'Honneur de la Ligue Aérienne d'Amérique.

LUNDI, 5IEME JOUR
Après-midi—Premier concours de Parachutes pour le Prix Bennett de $500.00.
Soir—Le grand dirigeable et sa valeur au point de vue transport. Les représentants des Compagnies de chemin de fer, d'Express, de Navigation et autres organisations de transports, sont invités à y assister.

MARDI, 6IEME JOUR
Après-midi—Conférences, accompagnées de projections sur la surveillance aérienne des forets. (Les membres du département forestier de chaque Etat sont invités).
Soir—Le rôle des escadrilles de police aérienne, et pourquoi chaque ville devrait en posséder.

MERCREDI, 7IEME JOUR
Après-midi—Journée de la poste aérienne. Conférences avec projections; considérations sur les avions postaux. Le Président du Comité des bureaux de poste et des voies postales au Sénat et à la chambre, et le Directeur Général des Postes, Burleson, sont invités à prononcer des discours. (26000 Directeur des Postes des Etats-Unis et des représentants des Chambres de Commerce de 13,000 villes y sont invités.)

JEUDI, 8IEME JOUR
Après-midi et soir—Discours avec projections sur la nécessité d'Aerodromes municipaux, et la part qui sera joué par l'aviation dans le "City Planning". (Les chambres de commerce et les commissions de City-planning" de 13000 villes sont invités.)

VENDREDI, 9IEME JOUR
Après-midi—Arrivée d'avions et hydravions militaires de leurs différents centres. Deuxième concours de Parachutes pour le prix Bennett de 500 dollars.
Soir—Conférences avec projections par des As célèbres, sur les derniers développements de la guerre aérienne et sur leurs aventures personneles.

SAMEDI, 10IEME JOUR
Après-midi—Journée, de la Marine et des fusillers marins. Concours aériens.
Soir—Réception d'officiers de l'Armée et de la Marine Américaine. Réception et discours au hall de l'Exposition Aeronautique sur la Jetée d'Acier.

DIMANCHE, 11IEME JOUR
Après-midi et soir—Presentation de drapeaux par chaque Etat des Etats Unis au escadrilles représentant les Etats-Chaque Etat offrira un drapeau à chaque escadrille dont la majorité des membres sont originaires de cet Etat. La présentation sera faite par les représentants, de l'Etat, de l'Aero Club, et de la branche de la Ligue Aérienne de cet Etat. (Tous les Etats et villes sont invités à envoyer des délégués, et l'Armée et la Marine à envoyer des représentants.)

LUNDI, 12IEME JOUR
Après-midi—Démonstration et conférences avec projections sur la valeur de l'Avion pour la publicité diurne et nocturne (Tous les agents et sociétés de publicité sont invités).
Soir—Transport aérien continental, Pan-Américaine. Discours par des membres des commissions de 20 Républiques latines-Américaines.

MARDI, 13IEME JOUR
Après-midi et soir—Transport aérien intercontinental Pan-Américaine. Discours par des membres des commissions de 20 Républiques Latines-Américaines.

MERCREDI ET JEUDI, 14IEME ET 15IEME JOUR
Après-midi et soir—Les voies aériennes et le transport aérien en Europe au Canada en Afrique en Australie et en Asie.

VENDREDI, 16IEME JOUR
Après-midi et soir—Instruments de Navigation aérienne pour voler au-dessus de la terre ou de l'eau (aviateurs, navigateurs, fabricants, d'instruments scientifiques et experts en aeronautique invités).

SAMEDI, 17IEME JOUR
Après-midi—Courses et concours aériens. Conférences et projections sur la photographie aérienne.
Soir—Exposition de photographies aériennes et d'appareils photographiques (Les photographes, professionels, et amateurs, et les fabricants d'appareils photographiques sont invités).

DIMANCHE, 18IEME JOUR
Après-midi et soir—Conférences sur la nécessité d'une attitude pluslarge en regard de l'assurance pour l'avion et les aviateurs.
Soir—Conférences avec projections. Comme quoi les mesures médicales et les inspections en vigueur dans l'armée diminuent les accidents. (Agents et compagnies d'assurance, invités).

MARDI, 20IEME JOUR
Après-midi et soir—Conférences avec projections, montrant les différentes routes aériennes pour traverser l'Atlantique, et les problèmes à résoudre pour accomplir la chose.

MERCREDI, 21IEME JOUR
Après-midi—Journée de la sureté de l'aviation. Discussions des mesures prises pour la sureté de l'aviation. Améliorations dans la construction d'avions. Sureté augmentée dans les moteurs d'avions. Dispositifs pour la sureté en vol.
Soir—Progrès faits dans l'art du pilotage d'avions. (Projections).

JEUDI 22IEME JOUR
Après-midi et soir—Conférences et discussions sur la Meteorologie. Comme quoi les bulletins meteorologiques peuvent être étendues et rendus plus efficaces par l'emploi de l'avion pour explorer les plus hautes couches de l'atmosphère. Comme quoi ces bulletins météorologiques sont d'assistance à la navigation aérienne. Les facteurs climatérique et télégraphiques et leur relations à l'aeronautique.

VENDREDI, 23IEME JOUR
Après-midi et soir—Conférences sur la jurisprudence aérienne. Lois et reglements sur le trafic aérien (1er jour). Avocats, commissaires de trafic, autorités de police de différents pays, invités.)

SAMEDI, 24IEME JOUR
Après-midi et soir—Courses et concours. Conférences avec projections sur la necessité d'etablir un niveau d'altitude pour la circulation aérienne, internationale, interstate et interurbaine.

DIMANCHE, 25IEME JOUR
Après-midi et soir—Journée artistique de l'Aéronautique. Discours sur la peinture et la sculpture aérienne; et exposition de peintures par Lieut. Farré, Lt. Ruttan et autres. (Artistes, Directeurs de Galleries d'Art et amateurs d'oeuvres artistiques, invités.)

LUNDI, 26IEME JOUR
Après-midi et soir—Problèmems aéronautiques et leurs solutions probables Ouverture du concours pour les idées et projets de grands avions.

MARDI, 27IEME JOUR
Après-midi—Facteurs qui augmentent l'efficacité des grands dirigeables.
Soir—Les avantages du plaquage et contre-plaquage dans la construction d'avion.

MERCREDI, 28IEME JOUR
Après-midi—Conférences sur le problème du vol à une altitude de ou supérieure à 25000 pieds et leur solutions probables.
Soir—Les moteurs d'avions actuels.

JEUDI, 29IEME JOUR
Après-midi—Hydravions versus avions pour le sport et le transport.
Soir—Concours pour les idées et projets de grands avions.

VENDREDI, 30IEME JOUR—"Memorial Day".
Après-midi—Courses de dirigeables; concours de rapidité d'ascension pour ballons captifs; concours de parachutes.
Soir—Réception au Hall de l'Aeronautique. Jetée d'acier.

SAMEDI, 31IEME JOUR
Après-midi—Concours d'avions, d'hydravions et de dirigeables. Concours d'aviettes auquel les cyclistes et les fabricants de cycles et motorcyclettes seront invités.
Soir—Aptitudes médicales pour les aviateurs de paix et de guerre. Rapports de différents pays, illustrés par des films intéressants (50,000 autorités médicales invités.)

DIMANCHE, 32IEME JOUR
Après-midi et soir—Remise des prix et diplômes pour tous concours et courses.

Le Gouvernement Français, les organisations aéronautiques, sportives, scientifiques, industrielles, et civiques de France sont invités à envoyer des représentants pour assister à cette grande convention aéronautique. En arrivant aux Etats Unis, ces représentants sont invités à se présenter à l'Etat Major du Comité de la Convention, au numéro 297, Madison Avenue, à New York pour se faire inscrire et recevoir leur insigne et le programme officiel.
Au cas où il leur serait plus facile de se rendre directement à Atlantic City, ils pourront s'y faire inscrire aux bureaux de la Convention, situés à l'un des Hotels suivants: Hotel Traymore, Hotel Chalfonte, The Breakers Hotel, Hotel St. Charles, Hotel Marlborough-Blenheim, Hotel Chelsea, Hotel Alamac, Hotel Dennis, et l'Hotel Haddon Hall.
Des représentants du Comité de la Convention seront aux bureaux de la convention aux hotels ci-dessus et délivreront les insignes officiels qui admettront les porteurs au Hall de l'aéronautique, à l'exposition sur la jetée d'acier, au stand des juges, pendant les concours, et à l'aérodrome et au centre d'hydravion où moteurs et machines seront démontrés.

Toutes comunications jusqu'au ler mai, devront être adressées au: Rear Admiral Peary, Chairman, Aeronautic Convention, Aero Club of America, 297 Madison Avenue, New York City.

LA SEGUNDA CONVENCION Y EXPOSICION AERONAUTICA PAN-AMERICANA

Celebrada Bajo Los Auspicios del "Aero Club of America," "The Aerial League of America" y "The Pan-American Aeronautic Federation".

Desde el Jueves Primero de Mayo Hasta el Primero de Junio, Ambos Inclusives de 1919 En Atlantic City, Estado de New Jersey, Estados Unidos de America

PROGRAMA

Concursos Que se Verificaran Todos Los Sabados:

(1) Concurso de Hidroaeroplanos (en general).
(2) Trofeo y Premios de Curtiss por Aviacion Maritima.
(3) Concurso de Hidroplanos Entre Universidades.
(4) Concurso de Aeroplanos Terrestres.
(5) Concurso de Globos Dirijibles.
(6) Concurso de Globos Sobre Velocidad en Ascender y Descender y sus Maniobras.
(7) Concurso de Paracaidas.
(8) Concurso de "Aviettes" (bicicletas y motocicletas con alas).

Programa Diario

(1) Exhibición de Aeroplanos, Motoras y sus Accesorias en el "Steel Pier."
(2) Demostracion y Ensayos de Hidroaeroplanos, Aeroplanos Terrestes, Motoras, Globos Dirijibles y Globos Cautivos, Para Compradores.
(3) Ascencion de Hidroplanos y Dirijibles con Pasajeros y Globos Cautivos.
(4) Vistas Cinematografas y Discursos Sobre Las Fases Mas Importantes de la Aeronautica, Como Siguen:

JUEVES PRIMER DIA

Apertura de la Convencion y Exposicion

EN LA TARDE—Recepcion en el salon aeronautico en el "Steel Pier." Discursos de los funcionarios del gobierno de los estados Unidos de America, del estado y de las sociedades aeronauticas.

EN LA NOCHE—Exposicion aeronautica y discursos de funcionarios.

VIERNES SEGUNDA DIA

EN LA TARDE—Exposicion aeronautica, ensayos preliminares de hidroplanos y globos dirijibles y cautivos.

EN LA NOCHE—Vistas cinematografas y discursos sobre aviacion de sport y paseo.

SABADA TERCER DIA

EN LA TARDE—Carreras de hidroaeroplanos y globos dirijibles y concurso en ascender y descender de globos cautivos.

EN LA NOCHE—Gran baile.

DOMINGO CUARTO DIA

EN LA MANANA—Serivios conmemorativos en honor de los aviadores difuntos por un prelado distinguido.

EN LA TARDE Y NOCHE—Recepcion a los aviadores mas renombrados aliados y a sus familiares y entrega de la medalla de valor del "Aero Club de America" y del diploma de honor de la "Aerial League de America."

LUNES QUINTO DIA

EN LA TARDE—Primer concurso de paracaidas por el premio de quinientos dollars de bennett.

EN LA NOCHE—El gran globo dirijible y su valor en la transportacion. Representantes de las empresas de ferrocarril, expreso, vapores y demas de transportes quedan invitados para asistir.

MARTES SESTO DIA

EN LA TARDE—Discursos con ilustraciones, de patrulla aeria de montes. (El departamento de montes de cada estado queda invitado.)

EN LA NOCHE—Trabajo de vigilancia policiaca aeria y razones por las cuales toda ciudad debe tener esta clase de servicio.

MIERCOLES SEPTIMO DIA

EN LA TARDE Y NOCHE—Dia de correos aerios. Discursos con ilustraciones y estudio de aeroplanos para servicio de correos. El presidente de la comision de correos de la camara de representantes y el de igual comite del senado asi como el ministro de comunicaciones de los Estados Unidos Sr. Burleson. Quedan invitados para dirijir la palabra. (Veinte seis mil administradores de coreo de los Estados Unidos y las camaras de comercio de trece mil ciudades quedan invitados para asistir.)

JUEVES OCTAVO DIA

EN LA TARDE Y NOCHE—Discursos con ilustraciones sobre las necesidades de aerodromos municipales y de la parte que debe tomar la aeronautica en los proyectos de ciudades. (Las camaras de comercio y las comisiones de proyectos de ciudades de 13,000 ciudades quedan invitadas para asistir.)

VIERNES NOVENO DIA

EN LA TARDE—Llegada de hidroplanos y aeroplanos del ejercito y la Marina de sus respectivas estaciones. Segundo concurso de paracaidas por el premio de $500 de Bennett.

EN LA NOCHE—Discursos con ilustraciones de los mas recientes desarollos en la guerra aeria y hazañas relatadas por famosos aviadores.

SABADO DECIMO DIA

EN LA TARDE—Dia del Ejercito y Marina. Concurso aeronautico.

EN LA NOCHE—Recepción a los oficiales de la Marina y Ejercito de los Estados Unidos. Recepción y discursos en el Salón de Exhibición Aeronautica en el "Steel Pier."

DOMINGO ONDECIMO DIA

EN LA TARDE Y NOCHE—Presentación de banderas por cada uno de los Estados de los Estados Unidos de America a sus respectivos escuadrones aereos. Cada Estado presentará una bandera al escuadron aereo respectivo que contenga el mayor número de naturales de aquel estado. La presentación se hara por los representantes del estado y del Club Aereo y Liga Aeria de aquel Estado. (Todos los Estados y ciudades quedan invitados para enviar sus delegados y el ejercito y marina para enviar representantes.)

LUNES DUODECIMO

EN LA TARDE—Demostraciones y discursos con ilustraciones sobre el valor de la aeronautica para anuncios de dia y de noche. (Todas personas y agentes dedicados al negocio de anuncios quedan invitados para asistir.)

EN LA NOCHE—Transporte aereo terrestre Pan-Americano. Discursos por los miembros de las Comisiones de las veinte Republicas Pan-Americanas.

MARTES DECIMO-TERCERO

EN LA TARDE Y NOCHE—Transporte aereo maritimo Pan-Americano. Discursos por los miembros de las Comisiones de las veinte Republicas Pan-Americanas.

MIERCOLES Y JUEVES DIAS 14 Y 15

EN LA TARDE Y POR LA NOCHE—Dias y transportes aereos en Europa, Canada, Africa, Australia y Asia.

VIERNES DIA 16

EN LA TARDE Y POR LA NOCHE—Instrumentos para la aviación terestre y marítima. (Aviadores, navegadores, fabricantes de instrumentos cientificos y peritos en aeronautica quedan invitados.)

SABADO DIA 17

POR LA TARDE—Carreras y concursos aereos. Discursos con ilustraciones sobre la fotografia aerea.

POR LA NOCHE—Exhibición extensa de fotografias aereas y aparatos fotográficos. (Fotografos, tanto los profesionales como los afisionados y fabricantes de aparats fotograficos quedan invitados.)

DOMINGO DIA 18

EN LA TARDE Y POR LA NOCHE—Discursos con ilustraciones sobre la exploración aerea y el uso de la aereonave para estudios geodéticos y de costas.

LUNES DIA 19

EN LA TARDE Y POR LA NOCHE—Discursos sobre la necesidad de un concepto mas ámplio relativo al seguro de aereonaves y aviadores.

POR LA NOCHE—Discursos con ilustraciones sobre la manera en que los requisitos e inspección medico-militares disminuyen el número de accidentes. (Compañias de seguros y agentes quedan invitados.)

MARTES DIA 20

EN LA TARDE Y POR LA NOCHE—Discursos con ilustraciones mostrando diferentes modos de cruzar el Mar Atlantico por el aire y los problemas que deben resolverse para realizar dicho objeto.

MIERCOLES DIA 21

EN LA TRADE—Dia de Seguridad Aerea. Discusiones sobre las disposiciones hechas para la sceguridad aerea; mejoras en la construcción de aeroplanos; aumento de estabilidad en las motoras aereas; divisas para aumentar la seguridad aerea.

EN LA NOCHE—Progreso realizado en el manejo de los aeroplanos (con ilustraciones).

JUEVES DIA 22

EN LA TARDE Y NOCHE—Discursos y discusiones sobre metereología-manera de extender los informes metereologicos y hacerlos mas eficaces mediante el uso de aeronaves en la exploración de las altas regiones del aire así como la manera en que los pronosticos metereologicos pueden ser de auxilio en la navegación aerea; y factores telegraficos y climaticos en relación a la aeronautica.

VIERNES DIA 23

EN LA TARDE Y NOCHE—Discursos sobre la jurisprudencia aerea-leyes aereas y reglamentación del trafico aereo (primer dia). (Abogados Jefes de Trafico y Autoridades Policiacas de los distintos paises quedan invitados.)

SABADO DIA 24

EN LA TARDE—Carreras y concursos.

EN LA NOCHE—Discursos con ilustraciones sobre la necesidad de establecer lineas de altitud para viajes internacionales, entre los estados y entre las ciudades por medio del aire.

DOMINGO DIA 25

EN LA TARDE Y NOCHE—Da de Arte Aeronautica. Discurso sobre la pintura y escultura aeronautica de los distintos paises y exhibición de los cuadros aereos por el Teniente Farré, Teniente Ruttan y otros. (Artistas prominetes y directores de Salones de Artes y demás interesados quedan invitados.)

SEMANA DE INGENIERIA.

LUNES DIA 26

EN LA TARDE—Problemas de ingenieria aeronautica y su porspectiva solución.

EN LA NOCHE—Apertura del Concurso para diseños e ideas sobre grandes aeroplanos.

MARTES DIA 27

EN LA TARDE—Factores que contribuyen al aumento de la eficiencia de los grandes globos dirijibles.

EN LA NOCHE—Ventajas de enchapear y de la madera denominada "plywood" en la construcción de aereonaves.

MIERCOLES DIA 28

EN LA TARDE—Discursos sobre los problemas de volar a una altura de 25,000 pies y mas, y su solución prospectiva.

EN LA NOCHE—Máquinas aereas de la actualidad.

JUEVES DIA 29

EN LA TARDE—Tema: "Flying-boats" contra hidroplanos para sport y transporte.

EN LA NOCHE—Concurso sobre diseños e ideas para grandes aeroplanos.

VIERNES DIA 30

EN LA TARDE—Carreras entre globos dirijibles, concurso de velocidad de ascender y descender de globos cautivos; concurso de paracaidas.

EN LA NOCHE—Recepción en el Salón Aeronautico en el "Steel Pier."

SABADO DIA 31

EN LA TARDE—Concursos de hidroplanos, aeroplanos, y globos dirijibles. Concurso de "Aviettes" al cual serán invitados todos los biciclistas y fabricantes de bicicletas y motocicletas.

EN LA NOCHE—Requisitos medicos para aviadores en tiempo de guerra y de paz. Informes de distintos paises ilustrados con vistas cinematografas de atractivo. (50,000 medicos quedan invitados.)

DOMINGO DIA 32.

EN LA TARDE Y NOCHE—Presentación de premios y diplomas de todos los concursos.

Los Gobiernos de la Argentina, Brasil, Bolivia, Chile, Colombia, Costa Rica, Cuba, República Dominicana, Ecuador, Honduras, Haiti, Panamá Guatemala, Paraguay, Perú, Portugal, El Salvador, Espaïna, Uruguay, Venezuela, Mejico, y Nicaragua, asi como las Sociedades Aeronaúticas, Deportivas, Cientificas, Industriales y Civicas, de los mismos paises, por la presente quedan invitadas para enviar representantes a asistir a eete gran concurso aeronaútico. Dichos representantes a su llegada a los Estados Unidos deberán presentarse a la oficina principal del Comité encargado de la Convención, en el número 297 Avenida de Madison, en la ciudad de New York, para inscribirse y al proprio tiempo recibir sus credenciales y copia del programa oficial.

En el caso de que les sea mas conveniente a algunos de los representantes ir directamente a Atlantic City, dichos señores podrán inscribirse en las oficinas de la Convención que estarán constituidas en dicho lugar en los siguientes hoteles: "Traymore," "Chalfonte," "The Breakers," "St. Charles," "Marlborough-Blenheim," "Chelsea," "Alamac," "Dennis" y "Haddon Hall."

En Comité de la Convención tendrá representantes en las oficinas de la Convención Aeronaútica en dichos hotelesquienes expedirán las credenciales o chapas oficiales de entrada al portador para el Salón Aeronaútico, la Exposi-ción Aeronaútica en el "Steel Pier," la sección apartada para los Jueces durante el concurso, y al "Aerodromo" yestaciones para hidroaeroplanos donde habrán exhibiciones de aeronaves y sus motoras.

Sírvase dirijir todas sus comunicaciones hasta el primero de Mayo Próximo venidero, al Sr. Contraalmirante Peary, en la forma siguiente: Rear Admiral Peary, Chairman, Aeronautic Convention, Aero Club of America, 297 Madison Avenue, New York City.

SECONDA CONVENZIONE ED ESPOSIZIONE AEREONAUTICA PAN-AMERICANA

Sotto gli Auspici dell'Aero Club of America, dell'Aerial League of America e della Federazione Aeronautica Pan-Americano

Dal Primo Maggio 1919, al Primo Giugno incluso,

ad

Atlantic City, N. J.

PROGRAMMA

GARE CHE AVRANNO LUOGO OGNISABATO

(1) Gare Idroplani (generale).
(2) Voli nautici apparecchio tipo Curtiss-Trofei e Premi.
(3) Gare Idroplani (Universita).
(4) Gare Aeroplani di terra.
(5) Gare Dirigibili.
(6) Gare Velocita ascesa e discesa, e manovre di Palloni frenati.
(7) Gare Paracadute.
(8) Aviette (Velocipedi e motocicli alati).

AVVENIMENTI QUOTIDIANI

(1) Esposizione di Aeroplani, Motori ed accessori sullo Steel Pier (Ponte d'Acciaio).

(2) Esercitazioni e prove idroplani, Aeroplani di terra, motori, Dirigibili, Palloni frenati.

(3) Trasporto Aereo passeggeri su Idroplani, e Dirigibili-Ascensioni Palloni frenati.

(4) Spettacolo cinematografico e discorsi sul elpiu importanti fasi dell'Aereonautica, nell'ordine seguente:

GIOVEDI, 1MO GIORNO

Apertura Convenzione ed Esposizione.

POMERIGGIO—Ricevimento nella Sala Aereonautica sullo Steel Pier. Conferenze Autorita Federali, Statali, ed Aereonautiche.

SERA—Esposizione Aereonautica e discorsi ufficiali.

VENERDI, 2DO GIORNO

POMERIGGIO—Esposizione Aereonautica—prove preliminari, idroplani, Dirigibili, e Palloni Frenati.

SERA—Cinema e conferenza-soggetto "Aereonautica Sportiva."

SABATO, 3O GIORNO

POMERIGGIO—Corse Idroplani e dirigibili; gare di velocitá ascesa e discesa Palloni frenati.

SERA—Ballo.

DOMENICO, 4TO GIORNO

MATTINO—Un eminente Ecclesiastico commemorerá gli Aviatori defunti.

POMERIGGIO E SERA—Ricevimento "Assi" alleati ed eroi dell'Aria e loro parenti—Annunzio conferimento medaglia al valore dell'Aero Club of A. e diploma d'onore dell'Aerial League of America.

LUNEDI, 5TO GIORNO

POMERIGGIO—Prima Gara Paracadute. Premio Bennett $500.

SERA—Il Dirigibile di grosse dimensioni e la sua utilitá per trasporti. Sono invitati i Sigg. Rappresentanti delle ferrovie, dell Compagnie di Express, delle Compagnie di Navigazione e di altri servizi-trasporti.

MARTEDI, 6TO GIORNO

POMERIGGIO—Conferenze con proiezioni sulla "Guardia Forestale Aerea" (Sono invitati i rappresentanti dei Dipartimenti forestali di ogni Stato.)

SERA—Polizia aerea (squadre) e le ragioni per le quali ogni cittá dovrebbe averne una.

MERCOLEDI, 7MO GIORNO

POMERIGGIO E SERA—Giornata "Posta Aerea". Conferenza con proiezioni—Considerazioni su la "posta aerea". Sono invitati a parlare: il Capo del Comitato ufficio Posta e servizio Stradale della Camera di Deputati e del Senato e il Direttore Generale della Posta, Sig. Burleson (26,000 impigati postali ed i rappresentanti delle Camere di Commercio di 13,000 cittá).

GIOVEDI, 8VO GIORNO

POMERIGGIO E SERA—Conferenza con proiezioni sulla necessitá di costruire aerodromi municipali e sull agrande influenza che gli aeroplani avranno nella costruzione e nello svliuppo delle nuove cittá. (Sono invitati i Commissari delle Camere di Commercio e degli uffici Planimetrici municipali di 13,000 cittá.)

VENERDI, 9O GIORNO

POMERIGGIO—Arrivo di Odroplani e di aeroplani dell'esercito da stazioni aeree dell'esercito e della marina. Seconda gara paracadute premio Bennett $500.00.

SERA—Conferenza con proiezioni sui recentissimi progressi della lotta aerea narrate da famosi "Assi."

SABATO, 10MO GIORNO

POMERIGGIO—Giornata in onore dell'esercito e della Marina—Gare Aeree e tornei.

SERA—Ricevimenti Sigg. Ufficiali dell'Esercito e della S. U. Trattenimento e discorsi nella sala dell'-Esposizione Aereonautica sullo Steel Pier.

DOMENICA, 11MO GIORNO

POMERIGGIO E SERA—Presentazione delle bandiere da parte di ciascun Stato degli S. U. alle squadre aeree che li rappresentano. Ciascun Stato presentera una bandiera a ciascuna squadra aerea, i membri della quale saranno possibilmente tutti nativi dello Stato che rappresentano. I rappresentanti delle succursali in ogni Stato dell'-Aereo Club e dell'Aerial League faranno tale rappresentazione. (Ciasun Stato e ciascuna cittá saranno invitati a mandare delegati e l'Esercito e la Marina a mandare rappresentanti.)

LUNEDI, 12MO GIORNO

POMERIGGIO—Conferenze illustrate sul valore della macchine deree come mezzi di "reclame" di giorno e di notto. (Sono invitati tutte le compagnie di pubblicita nazionali ed estere.)

SERA—Trasporto Aereo Pan-Americano su terra. Conferenze di membri delle Commissioni delle venti repubbliche America-latine.

MARTEDI, 13MA GIORNATA

POMERIGGIO E SERA—Trasporto Aereo Pan-Americano sopra acqua. Conferenze di membri delle Commissioni delle venti repubbliche Americo-Latine.

MERCOLEDI, E GIOVEDI, 14MO E 15MO GIORNO

POMERIGGIO E SERA—Le Vie Aeree ed il Trasporto Aereo in Europa, Canada, Africa, Australia ed Asia.

VENERDI, 16MO GIORNO

POMERIGGIO E SERA—Istrumenti di navigazione Aerea per voli sopra terra e sopra mare. (Sono invitati aviatori, naviganti, fabbricanti strumenti scientifici a periti aereonautici.)

SABATO, 17MO GIORNO

POMERIGGIO—Corse e gare aerenautiche. Conferenze con proiezioni sul l'Arte Fotografica Aerea.

SERA—Esposizione su vasta scala di Fotografie Aeree e di apparati fotografici. (Sono invitati tutti i fotografi, professionisti e dilettanti, e fabbricanti di apparati fotografici.)

DOMENICA, 18MO GIORNO

POMERIGGIO E SERA—Conferenze Illustrate con proiezioni sull'Esplorazione Aerea e sull'uso di velivoli per le misurazioni costiere e geodetiche.

LUNEDI, 19MO GIORNO

POMERIGGIO—Conferenze sul bisogno di un miglior trattamente da parte delle Compagnie d'Assicurazione nelle condizioni di assicurazione delle macchine e degli aviatori.

SERA—Conferenze con proiezioni sull'influenza che i sistemi del Corpo Medico dell'Esercito hanno sulla diminuzione delle disgrazie. (Sono invitati tuttigli agenti delle Compagnie di Assicurazione.)

MARTEDI, 20MO GIORNO

POMERIGGIO E SERA—Conferenze Illustrate indicanti i vari modi gi studiati per attraversare l'Atlantico nell'Aria—ostacoli da vincere, problemi da risolvere per poter compiere felicemente il viaggio.

MERCOLEDI, 21MO GIORNO

POMERRIGIO—Giornata dedicata alla sicurezza Aerea—Discussioni su provvedimenti presi per la sicurezza Aerea—Perfezionamenti nella costruzione degli aereoplani; Aumentata sicurezza di motori aerei; congegni atti a migliorare la stabilitá dei voli.

SERA—Progressi fatti nell'arte dei piloti aviatori. (Illustrazioni.)

GIOVEDI, 22MO GIORNO

POMERIGGIO E SERA—Conferenze e discorsi di meteorologia; come possono essere fatte piu esattamente le previsioni meterorologiche esplorando l'aria con velivoli negli strati superiori, e come queste previsioni meteorologiche possono essere utili alla nagivazione aerea—Fattori telegrafici e climatici in relazione all'Aereonautica.

VENERDI, 23MO GIORNO

POMERIGGIO E SERA—Conferenze sulla giurisprudenza aerea; leggi e regolamenti per il traffico Aereo. (Avvocati, Commissario di traffico, Autorita di Polizia dei differenti paesi invitati.)

SABATO, 24MO GIORNO

POMERIGGIO E SERA—Corse e gare—Conferenze illustrate sul bisogno di stabilire un livello di altezza per il traffico aereo internazionale, interstatale, e interurbano.

DOMENICA, 25MO GIORNO

POMERIGGIO E SERA—Giornata d'Arta Aeronautica. Conferenze sulla Pittura e sulla Scultura di ogni paese su soggetti d'Aereonautica. Esposizione di quadri di soggetto dei tenenti Farre, Ruttan, e di altri. (Sono invitati tutti i piú Valenti artisti, i direttori di Gallerie d'Arte e gli amatori d'Arte.)

SETTIMANA DEDICATA ALLA "MECCANICA"

LUNEDI, 26MO GIORNO

POMERIGGIO—Problemi di meccanica aeronautica e la loro probabile soluzione.

SERA—Apertura di un concorso—disegni ed idee per la costruzione di grandi aeroplani.

MARTEDI, 27MO GIORNO

POMERIGGIO—Fattori che possono aumentare l'efficienza di grandi dirigibili.

SERA—Vantaggi del legno compensato per la costruzione di velivoli.

MERCOLEDI, 28MO GIORNO

POMERIGGIO—Conferenze sui problemi che si affacciano per voli a 25,000 piedi a piu e la loro probabile soluzione.

SERA—Macchine aere d'oggi.

GIOVEDI, 29MO GIORNO

POMERIGGIO—Battelli volanti contro Idroplani per Sport e per trasporti commerciali.

SERA—Gare—Disegni ed idee per aeroplani di grandi dimensioni.

VENERDI, 30MO GIORNO (Giorno Commemorativo)

POMERIGGIO—Corse Dirigibili—Gare di velocita d'ascensione tra palloni frenati—Gara paracadute.

SERA—Grande ricevimento nella Aereonautic Hall, Steel Pier.

SABATO, 31MO GIORNO

POMERIGGIO—Gare tra idroplani, aereoplani dirigibili—Gara Aviette alla quale interveranno tutti i ciclisti ed i fabbricanti di biciclette e di motociclette.

SERA—Sistemi e regolamentari medici internazionali per aviatori in guerro ed in pace. Relazioni sui sistemi adottati nei differenti paesi, illustrate da interessanti proiezioni. (Sono invitati 50,000 Sanitari.

DOMENICA, 32MO GIORNO

POMERIGGIO E SERA—Distribuzione generale dei diplomi.

Il Governo d'Italia e le organizzazioni italiane di Aeronautica di Sport e di Scienze sono invitati a mandare rappresentanti ad assistere a questo grande evento aereonautico. Arrivando negli Stati Uniti i Signori Rappresentanti dovranno presentarsi al Quartiere Generale del Somitato al N. 297 Madison Ave., N. Y., per registrarsi e ricevere la targhetta ufficiale, nonché il programma.

Nel caso fosse per loro piú conveniente recarsi direttamente ad Atlantic City, potranno registrarsi colá presso gli uffici situati nei seguenti alberghi: Hotel Traymore, Hotel Chalfonte, The Breakers Hotel, Hotel St. Charles, Hotel Marlborough-Blenheim, Hotel Chelsea, Hotel Alamac, Hotel Dennis and Hotel Haddon Hall.

I Rappresentanti del Comitato di Convenzione si troveranno negli uffici della Convenzione Aereonautica nei sunnominati Alberghi e distribuiranno i distintivi ufficiali che daranno al portatore il diritto di essere ammesso all'Aereonautic Hall, all'Esposizione sullo Steel Pier, nel recinto occupato dai giudici durante la gara, all'Aerodromo, all stazione degli idroplani dove saranno esibiti i velivoli ed i motori.

Ogni comunicazione sino al primo Marzo dovrá essere indirizzata al Rear Admiral Peary, Chairman, Aeronautic Convention, Aero Club of America, N. 297 Madison Ave., New York.

S. V. A.

The Plane Which Flew Over Vienna

A squadron of seven S. V. A. machines flew from Venice over Vienna, a distance of seven hundred miles--6 2-3 hours in the air--one of the most notable long-distance flight achievements of the war in the air.

TRADE MARK

You're Looking at the Inside of a Goodrich Dirigible

Yes, and this is but one of the eight giant dirigibles built by Goodrich for Uncle Sam.

Not to mention 362 kite or observation craft, ten supply and three huge target balloons.

Or those big, billowy Silvertown Cord Airplane tires that made landing a pleasure instead of a menace after a night bombing raid.

And yet, dramatic as is this chapter, the lion's share of Goodrich energy was expended in producing gas masks, rubber boots, truck and pneumatic tires, raincoats and ponchos, tubing, insulated wire, mechanical and surgical goods for the lads who wallowed through the muck of the trenches.

All of which emphasizes the tremendous resources turned to the nation for the readjustment period.

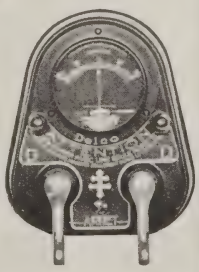
GOODRICH

RUBBER GOODS

Photograph of order issued by the Lorraine-Dietrich Company, countersigned by the French Government, Department of Motors and the Division of Magnetos requiring delivery of 1,000 Delco Ignition Systems to supplant standard magneto equipment on the latest French aeroplane motors.



Such an order was quite unprecedented in Europe of course—but War cannot respect custom nor play favorites. It always demands the fittest and best. So as the war went on, our Veteran Allies, taking their cue from the performance of American battle planes, *also* recognized the supremacy of Delco Ignition for the strenuous airplane service.

The Dayton Engineering Laboratories Company

The Meissner Airfone

A Certain Means of Verbal Communication While in Flight

The AIRFONE provides a really practical and satisfactory means for intelligible conversation between occupants of aircraft and is especially valuable in training the student pilots.

A distinctive advantage of the AIRFONE is the elimination of all vibration and engine noises during conversation.

The AIRFONE is highly endorsed by many army and navy aviators.
